LM25116 ワイドレンジ同期整流降圧型コントローラ

1 特長
- エミュレーテッド・ピーク電流モード
- 広い動作電圧範囲 (最大42V)
- 低いシャットダウン時 IQ (10µA未満)
- 標準または論理レベルMOSFETを駆動
- 堅牢な3.5Aピーク・ゲート駆動
- フリーランまたは1MHzへの同期動作
- (オプション)ダイオード・エミュレーション・モード
- 出力を1.215V〜36Vの範囲でプログラム可能
- 精度1.5%の基準電圧
- 電流制限をプログラム可能
- プログラム可能なソフト・スタート
- 電圧を設定可能なライン電圧誤動作防止
- 外部バイアス電源への自動切り替え
- 20ピンのHTSSOP露出パッド
- サーマル・シャットダウン

2 アプリケーション
- 車載インフォテインメント
- 産業用DC-DCモータ・ドライバ
- 車載用USBアダプタ
- テレコム・サーバー

3 概要
LM25116は降圧レギュレータ・アプリケーション用に開発された同期整流降圧型コントローラで、高電圧または電圧の変動幅が大きい入力を対象としています。制御方式は電流モード制御を基礎とするもので、エミュレートされた電流ランプを使用して動作します。電流モード制御には、ライン・フィードフォワードと、サイクル単位の電流制限が組み込まれており、ループ補償が容易に行えます。エミュレートされた制御ランプを使用することで、パルス幅変調回路のノイズ感受性を減少し、入力電圧の高いアプリケーションで不可欠となる、デューティサイクルの微細な制御を容易に実行できます。動作周波数は50kHz〜1MHzの範囲で設定可能です。LM25116はアダプティブ・デッドタイム制御を用いて、ハイサイドとローサイドの外付けNMOSワラスイッチを駆動します。不連続モードでの動作によって軽負荷時の効率を高めるダイオード・エミュレーション・モードは、ユーザーが選択できます。静止電流を制限するために、シャットダウン時はコントローラがディセーブルされ、合計入力電流が10µA未満に低下します。追加機能として、高電圧のバイアス・レギュレータ、外部バイアスへの自動切り替えによる効率性向上、サーマル・シャットダウン、周波数同期、サイクル単位の電流制限、可変のライン電圧誤動作防止が搭載されています。このデバイスは、放熱を助ける露出ダイ接続パッドを増幅して消費可能電力を増大させた20ピンHTSSOPパッケージで供給されます。

(1) Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under Recommended Operating Conditions. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

(2) These pins must not exceed VIN.

6.2 ESD Ratings

<table>
<thead>
<tr>
<th>(V_{(ESD)}) Electrostatic discharge</th>

7 Detailed Description

7.1 Overview

The LM25116 high-voltage switching regulator features all of the functions necessary to implement an efficient high-voltage buck regulator using a minimum of external components. This easy-to-use regulator integrates high-side and low-side MOSFET drivers capable of supplying peak currents of 2 A. The regulator control method is based on current mode control using an emulated current ramp. Emulated peak current mode control provides inherent line feedforward, cycle-by-cycle current limiting and ease of loop compensation. The use of an emulated control ramp reduces noise sensitivity of the pulse-width modulation circuit, allowing reliable processing of the very small duty cycles necessary in high input voltage applications. The operating frequency is user programmable from 50 kHz to 1 MHz. An oscillator or synchronization pin allows the operating frequency to be set by a single resistor or synchronized to an external clock. Fault protection features include current limiting, thermal shutdown and remote shutdown capability. An undervoltage lockout input allows regulator shutdown when the input voltage is below a user-selected threshold, and an enable function puts the regulator into an extremely low current shutdown through the enable input. The 20-pin HTSSOP package features an exposed pad to aid in thermal dissipation.

7.2 Functional Block Diagram
7.3 Feature Description

7.3.1 High-Voltage Start-Up Regulator

The LM25116 contains a dual mode internal high-voltage start-up regulator that provides the VCC bias supply for the PWM controller and a bootstrap gate drive for the high-side buck MOSFET. The input pin (VIN) can be connected directly to an input voltage source as high as 42 V. For input voltages below 10.6 V, a low dropout switch connects VCC directly to VIN. In this supply range, VCC is approximately equal to VIN. For VIN voltages greater than 10.6 V, the low dropout switch is disabled and the VCC regulator is enabled to maintain VCC at approximately 7.4 V. The wide operating range of 6 V to 42 V is achieved through the use of this dual mode regulator.

Upon power up, the regulator sources current into the capacitor connected to the VCC pin. When the voltage at the VCC pin exceeds 4.5 V and the UVLO pin is greater than 1.215 V, the output switch is enabled and a soft-start sequence begins. The output switch remains enabled until VCC falls below 4.5 V, EN is pulled low, the UVLO pin falls below 1.215 V, or the die temperature exceeds the thermal limit threshold.

An output voltage derived bias supply can be applied to the VCCX pin to reduce the IC power dissipation. If the bias supply voltage is greater than 4.5 V, the internal regulator essentially shuts off, reducing the IC power dissipation. The VCC regulator series pass transistor includes a diode between VCC and VIN that must not be forward biased in normal operation. For an output voltage between 5 V and 15 V, VOUT can be connected directly to VCCX. For VOUT < 5 V, a bias winding on the output inductor can be added to VOUT. If the bias winding can supply VCCX greater than VIN, an external blocking diode is required from the input power supply to the VIN pin to prevent VCC from discharging into the input supply.

The output of the VCC regulator is current limited to 15 mA minimum. The VCC current is determined by the MOSFET gate charge, switching frequency and quiescent current (see MOSFETs in the Typical Application). If VCCX is powered by the output voltage or an inductor winding, the VCC current must be evaluated during start-up to ensure that it is less than the 15 mA minimum current limit specification. If VCCX is powered by an external regulator derived from VIN, there is no restriction on the VCC current.

In high-voltage applications, take extra care to ensure the VIN pin does not exceed the absolute maximum voltage rating of 45 V. During line or load transients, voltage ringing on the VIN line that exceeds values listed in Absolute Maximum Ratings can damage the IC. Both careful PCB layout and the use of quality bypass capacitors placed close to the VIN and GND pins are essential.
Feature Description (continued)

7.3.2 Enable

The LM25116 contains an enable function allowing a very low input current shutdown. If the enable pin is pulled below 0.5 V, the regulator enters shutdown, drawing less than 10 µA from the VIN pin. Raising the EN input above 3.3 V returns the regulator to normal operation. The maximum EN transition time for proper operation is one switching period. For example, the enable rise time must be less than 4 µs for 250-kHz operation.

A 1-MΩ pullup resistor to VIN can be used to interface with an open collector control signal. At low input voltage the pullup resistor may be reduced to 100 kΩ to speed up the EN transition time. The EN pin can be tied directly to VIN if this function is not required. It must not be left floating. If low-power shutdown is not required, the UVLO pin must be used as an on/off control.

Figure 27. Enable Circuit

Figure 28. EN Bias Current vs Voltage
Feature Description (continued)

7.3.3 UVLO
An undervoltage lockout pin is provided to disable the regulator without entering shutdown. If the UVLO pin is pulled below 1.215 V, the regulator enters a standby mode of operation with the soft-start capacitor discharged and outputs disabled, but with the VCC regulator running. If the UVLO input is pulled above 1.215 V, the controller resumes normal operation. A voltage divider from input to ground can be used to set a VIN threshold to disable the supply in brown-out conditions or for low input faults. The UVLO pin has a 5-µA internal pullup current that allows this pin to left open if the input undervoltage lockout function is not required. For applications which require fast on or off cycling, the UVLO pin with an open collector control signal may be used to ensure proper start-up sequencing.

The UVLO pin is also used to implement a *hiccup* current limit. If a current limit fault exists for more than 256 consecutive clock cycles, the UVLO pin is internally pulled down to 200 mV and then released, and a new SS cycle initiated. A capacitor to ground connected to the UVLO pin sets the timing for hiccup mode current limit. When this feature is used in conjunction with the voltage divider, a diode across the top resistor may be used to discharge the capacitor in the event of an input undervoltage condition. There is a 5-µs filter at the input to the fault comparator. At higher switching frequency (greater than approximately 250 kHz) the hiccup timer may be disabled if the fault capacitor is not used.

7.3.4 Oscillator and Sync Capability
The LM25116 oscillator frequency is set by a single external resistor connected between the RT/SYNC pin and the AGND pin. The resistor must be placed very close to the device and connected directly to the pins of the IC (RT/SYNC and AGND). To set a desired oscillator frequency ($f_{SW}$), the necessary value for the resistor can be calculated from Equation 1.

$$R_T = \frac{T - 450 \text{ ns}}{284 \text{ pF}}$$

where
- $T = 1 / f_{SW}$
- $R_T$ is in $\Omega$
- 450 ns represents the fixed minimum off time

The LM25116 oscillator has a maximum programmable frequency that is dependent on the VCC voltage. If VCC is above 6 V, the frequency can be programmed up to 1 MHz. If VCCX is used to bias VCC and VCCX < 6 V, the maximum programmable oscillator frequency is 750 kHz.

The RT/SYNC pin can be used to synchronize the internal oscillator to an external clock. The external clock must be a higher frequency than the free-running frequency set by the RT resistor. The internal oscillator can be synchronized to an external clock by AC coupling a positive edge into the RT/SYNC pin. The voltage at the RT/SYNC pin is nominally 1.215 V and must exceed 4 V to trip the internal synchronization pulse detection. A 5-V amplitude signal and 100-pF coupling capacitor are recommended. The free-running frequency must be set nominally 15% below the external clock. Synchronizing above twice the free-running frequency may result in abnormal behavior of the pulse width modulator.

7.3.5 Error Amplifier and PWM Comparator
The internal high-gain error amplifier generates an error signal proportional to the difference between the regulated output voltage and an internal precision reference (1.215 V). The output of the error amplifier is connected to the COMP pin allowing the user to provide loop compensation components, generally a type II network. This network creates a pole at very low frequency, a mid-band zero, and a noise reducing high frequency pole. The PWM comparator compares the emulated current sense signal from the RAMP generator to the error amplifier output voltage at the COMP pin.

7.3.6 Ramp Generator
The ramp signal used in the pulse width modulator for current mode control is typically derived directly from the buck switch current. This switch current corresponds to the positive slope portion of the inductor current. Using this signal for the PWM ramp simplifies the control loop transfer function to a single pole response and provides inherent input voltage feedforward compensation. The disadvantage of using the buck switch current signal for PWM control is the large leading edge spike due to circuit parasitics that must be filtered or blanked. Also, the
Feature Description (continued)

current measurement may introduce significant propagation delays. The filtering, blanking time and propagation
delay limit the minimal achievable pulse width. In applications where the input voltage may be relatively large in
comparison to the output voltage, controlling small pulse widths and duty cycles is necessary for regulation. The
LM25116 uses a unique ramp generator which does not actually measure the buck switch current but rather
reconstructs the signal. Representing or emulating the inductor current provides a ramp signal to the PWM
comparator that is free of leading edge spikes and measurement or filtering delays. The current reconstruction is
comprised of two elements, a sample-and-hold DC level and an emulated current ramp.

![Composition of Current Sense Signal](image)

The sample-and-hold DC level is derived from a measurement of the recirculating current through either the low-
side MOSFET or current sense resistor. The voltage level across the MOSFET or sense resistor is sampled and
held just prior to the onset of the next conduction interval of the buck switch. The current sensing and sample-
and-hold provide the DC level of the reconstructed current signal. The positive slope inductor current ramp is
emulated by an external capacitor connected from the RAMP pin to the AGND and an internal voltage controlled
current source. The current source that emulates the inductor current is a function of the VIN and VOUT
voltages per Equation 2.

\[ I_{\text{IN}} = 5 \, \mu\text{A/V} \times (\text{VIN} - \text{VOUT}) + 25 \, \mu\text{A} \] (2)

Proper selection of the RAMP capacitor \( C_{\text{RAMP}} \) depends upon the value of the output inductor \( L \) and the
current sense resistor \( R_S \). For proper current emulation, the DC sample and hold value and the ramp amplitude
must have the same dependence on the load current. That is in Equation 3.

\[
R_S \times A = \frac{g_m \times L}{C_{\text{RAMP}}}, \quad \text{so} \\
C_{\text{RAMP}} = \frac{g_m \times L}{A \times R_S}
\]

where

- \( g_m \) is the ramp generator transconductance (5 \( \mu\text{A/V} \))
- \( A \) is the current sense amplifier gain (10 V/V).

The ramp capacitor must be placed very close to the device and connected directly to the pins of the IC (RAMP
and AGND).

The difference between the average inductor current and the DC value of the sampled inductor current can
cause instability for certain operating conditions. This instability is known as subharmonic oscillation, which
occurs when the inductor ripple current does not return to its initial value by the start of next switching cycle.
Subharmonic oscillation is normally characterized by observing alternating wide and narrow pulses at the switch
node. Adding a fixed slope voltage ramp (slope compensation) to the current sense signal prevents this
oscillation. The 25 \( \mu\text{A} \) of offset current provided from the emulated current source adds the optimal slope
compensation to the ramp signal for a 5-V output. For higher output voltages, additional slope compensation may
be required. In these applications, a resistor is added between RAMP and VCC to increase the ramp slope
compensation.
Figure 30. R\textsubscript{DS(ON)} Current Sensing without Diode Emulation

The DC current sample is obtained using the CS and CSG pins connected to either a source sense resistor (R\textsubscript{S}) or the R\textsubscript{DS(ON)} of the low-side MOSFET. For R\textsubscript{DS(ON)} sensing, R\textsubscript{S} = R\textsubscript{DS(ON)} of the low-side MOSFET. In this case it is sometimes helpful to adjust the current sense amplifier gain (A) to a lower value to obtain the desired current limit. Adding external resistors R\textsubscript{G} in series with CS and CSG, the current sense amplifier gain A becomes Equation 4.

\[
A = \frac{10k}{1k + R\textsubscript{G}}
\]

(4)

7.3.7 Current Limit

The LM25116 contains a current limit monitoring scheme to protect the circuit from possible overcurrent conditions. When set correctly, the emulated current sense signal is proportional to the buck switch current with a scale factor determined by the current limit sense resistor. The emulated ramp signal is applied to the current limit comparator. If the emulated ramp signal exceeds 1.6 V, the current cycle is terminated (cycle-by-cycle current limiting). Because the ramp amplitude is proportional to V\textsubscript{IN} – V\textsubscript{OUT}, if V\textsubscript{OUT} is shorted, there is an immediate reduction in duty cycle. To further protect the external switches during prolonged current limit conditions, an internal counter counts clock pulses when in current limit. When the counter detects 256 consecutive clock cycles, the regulator enters a low power dissipation hiccup mode of current limit. The regulator is shut down by momentarily pulling UVLO low, and the soft-start capacitor discharged. The regulator is restarted with a full soft-start cycle once UVLO charges back to 1.215 V. This process is repeated until the fault is removed. The hiccup off-time can be controlled by a capacitor to ground on the UVLO pin. In applications with low output inductance and high input voltage, the switch current may overshoot due to the propagation delay of the current limit comparator. If an overshoot must occur, the sample-and-hold circuit detects the excess recirculating current. If the sample-and-hold DC level exceeds the internal current limit threshold, the buck switch is disabled and skip pulses until the current has decayed below the current limit threshold. This approach prevents current runaway conditions due to propagation delays or inductor saturation because the inductor current is forced to decay following any current overshoot.

Figure 31. Current Limit and Ramp Circuit
Feature Description (continued)

Using a current sense resistor in the source of the low-side MOSFET provides superior current limit accuracy compared to $R_{\text{DS(ON)}}$ sensing. $R_{\text{DS(ON)}}$ sensing is far less accurate due to the large variation of MOSFET $R_{\text{DS(ON)}}$ with temperature and part-to-part variation. The CS and CSG pins must be Kelvin connected to the current sense resistor or MOSFET drain and source.

The peak current which triggers the current limit comparator is calculated with Equation 5.

$$I_{\text{PEAK}} = \frac{1.1V - \frac{25 \mu A \times I_{\text{ON}}}{C_{\text{RAMP}}}}{A \times R_S} = \frac{1.1V}{A \times R_S}$$

where

- $t_{\text{ON}}$ is the on-time of the high-side MOSFET

The 1.1-V threshold is the difference between the 1.6-V reference at the current limit comparator and the 0.5-V offset at the current sense amplifier. This offset at the current sense amplifier allows the inductor ripple current to go negative by $0.5 V / (A \times R_S)$ when running full synchronous operation.

Current limit hysteresis prevents chatter around the threshold when VCCX is powered from VOUT. When $4.5 V < VCC < 5.8 V$, the 1.6-V reference is increased to 1.72 V. The peak current which triggers the current limit comparator becomes Equation 6.

$$I_{\text{PEAK}} = \frac{1.22V - \frac{25 \mu A \times I_{\text{ON}}}{C_{\text{RAMP}}}}{A \times R_S} = \frac{1.22V}{A \times R_S}$$

This has the effect of a 10% foldback of the peak current during a short circuit when VCCX is powered from a 5-V output.

7.3.8 HO Output

The LM25116 contains a high current, high-side driver and associated high-voltage level shift. This gate driver circuit works in conjunction with an external diode and bootstrap capacitor. A 1-µF ceramic capacitor, connected with short traces between the HB pin and SW pin, is recommended. During the off-time of the high-side MOSFET, the SW pin voltage is approximately –0.5 V and the bootstrap capacitor charges from VCC through the external bootstrap diode. When operating with a high PWM duty cycle, the buck switch is forced off each cycle for 450 ns to ensure that the bootstrap capacitor is recharged.

The LO and HO outputs are controlled with an adaptive deadtime methodology which insures that both outputs are never enabled at the same time. When the controller commands HO to be enabled, the adaptive block first disables LO and waits for the LO voltage to drop below approximately 25% of VCC. HO is then enabled after a small delay. Similarly, when HO turns off, LO waits until the SW voltage has fallen to ½ of VCC. LO is then enabled after a small delay. In the event that SW does not fall within approximately 150 ns, LO is asserted high. This methodology insures adequate dead-time for appropriately sized MOSFETs.

In some applications it may be desirable to slow down the high-side MOSFET turnon time to control switching spikes. This may be accomplished by adding a resistor in series with the HO output to the high-side gate. Values greater than 10 Ω must be avoided so as not to interfere with the adaptive gate drive. Use of an HB resistor for this function must be carefully evaluated so as not cause potentially harmful negative voltage to the high-side driver, and is generally limited to 2.2 Ω maximum.

7.3.9 Thermal Protection

Internal thermal shutdown circuitry is provided to protect the integrated circuit in the event the maximum junction temperature is exceeded. When activated, typically at 170°C, the controller is forced into a low power reset state, disabling the output driver and the bias regulator. This is designed to prevent catastrophic failures from accidental device overheating.
7.4 Device Functional Modes

7.4.1 Soft Start and Diode Emulation

The soft start feature allows the regulator to gradually reach the initial steady state operating point, thus reducing start-up stresses and surges. The LM25116 regulates the FB pin to the SS pin voltage or the internal 1.215-V reference, whichever is lower. At the beginning of the soft-start sequence when SS = 0 V, the internal 10-µA soft-start current source gradually increases the voltage of an external soft-start capacitor (C_{SS}) connected to the SS pin resulting in a gradual rise of FB and the output voltage.

During this initial charging of C_{SS} to the internal reference voltage, the LM25116 forces diode emulation. That is, the low-side MOSFET turns off for the remainder of a cycle if the sensed inductor current becomes negative. The inductor current is sensed by monitoring the voltage between SW and DEMB. As the SS capacitor continues to charge beyond 1.215 V to 3 V, the DEMB bias current increases from 0 µA up to 40 µA. With the use of an external DEMB resistor (R_{DEMB}), the current sense threshold for diode emulation increases resulting in the gradual transition to synchronous operation. Forcing diode emulation during soft start allows the LM25116 to start up into a prebiased output without unnecessarily discharging the output capacitor. Full synchronous operation is obtained if the DEMB pin is always biased to a higher potential than the SW pin when LO is high. R_{DEMB} = 10 kΩ bias the DEMB pin to 0.45 V minimum, which is adequate for most applications. The DEMB bias potential must always be kept below 2 V. At very light loads with larger values of output inductance and MOSFET capacitance, the switch voltage may fall slowly. If the SW voltage does not fall below the DEMB threshold before the end of the HO fall to LO rise dead time, switching defaults to diode emulation mode. When R_{DEMB} = 0 Ω, the LM25116 always runs in diode emulation.

Once SS charges to 3 V the SS latch is set, increasing the DEMB bias current to 65 µA. An amplifier is enabled that regulates SS to 160 mV above the FB voltage. This feature can prevent overshoot of the output voltage in the event the output voltage momentarily dips out of regulation. When a fault is detected (VCC undervoltage, UVLO pin < 1.215 V, or EN = 0 V) the soft-start capacitor is discharged. Once the fault condition is no longer present, a new soft-start sequence begins.
8 Application and Implementation

NOTE
Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI’s customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

8.1 Application Information
The LM25116 device is a step-down DC-DC controller. The device is typically used to convert a higher voltage DC voltage to a lower DC voltage. Use the following design procedure to select component values. Alternately, use the WEBENCH software to generate a complete design. The WEBENCH software uses an iterative design procedure and assesses a comprehensive database of components when generating a design.

8.2 Typical Application

Figure 33. 5-V, 7-A Typical Application Schematic

8.2.1 Design Requirements
Figure 33 is configured with the following specifications:
• Output voltage = 5 V
• Input voltage = 7 V to 42 V
• Maximum load current = 7 A
• Switching frequency = 250 kHz

8.2.2 Detailed Design Procedure
The bill of materials for this design are listed in Table 1.
Typical Application (continued)

Simplified equations are used as a general guideline for the design method. Comprehensive equations are provided in Comprehensive Equations.

8.2.2.1 Timing Resistor

$R_T$ sets the oscillator switching frequency. Generally, higher frequency applications are smaller but have higher losses. Operation at 250 kHz was selected for this example as a reasonable compromise for both small size and high efficiency. The value of $R_T$ for 250-kHz switching frequency can be calculated with Equation 7.
\[ R_T = \frac{250 \text{ kHz}}{284 \text{ pF}} = 12.5 \text{ k}\Omega \]  

(7)

The nearest standard value of 12.4 k\(\Omega\) was chosen for \(R_T\).

8.2.2.2 Output Inductor

The inductor value is determined based on the operating frequency, load current, ripple current and the input and output voltages.

Knowing the switching frequency (\(f_{SW}\)), maximum ripple current (\(I_{PP}\)), maximum input voltage (\(V_{IN(MAX)}\)) and the nominal output voltage (\(V_{OUT}\)), the inductor value is calculated with Equation 8.

\[
L = \frac{V_{OUT}}{I_{PP} \times f_{SW}} \times \left(1 - \frac{V_{OUT}}{V_{IN(MAX)}}\right) 
\]

(8)

The maximum ripple current occurs at the maximum input voltage. Typically, \(I_{PP}\) is 20\% to 40\% of the full load current. When running diode emulation mode, the maximum ripple current must be less than twice the minimum load current. For full synchronous operation, higher ripple current is acceptable. Higher ripple current allows for a smaller inductor size, but places more of a burden on the output capacitor to smooth the ripple current for low output ripple voltage. For this example, 40\% ripple current is chosen for a smaller sized inductor in Equation 9.

\[
L = \frac{5V}{0.4 \times 7A \times 250kHz} \times \left(1 - \frac{5V}{42V}\right) = 6.3 \mu H
\]

(9)

The nearest standard value of 6 \(\mu H\) is used. The inductor must be rated for the peak current to prevent saturation. During normal operation, the peak current occurs at maximum load current plus maximum ripple. During overload conditions with properly scaled component values, the peak current is limited to \(V_{CS(TH)}/R_S\) (See Current Sense Resistor). At the maximum input voltage with a shorted output, the valley current must fall below \(V_{CS(TH)}/R_S\) before the high-side MOSFET is allowed to turn on. The peak current in steady state increases to \(V_{IN(MAX)} \times t_{ON(min)}/L\) above this level. The chosen inductor must be evaluated for this condition, especially at elevated temperature where the saturation current rating may drop significantly.

8.2.2.3 Current Sense Resistor

The current limit is set by the current sense resistor value (\(R_S\)) in Equation 10.

\[
l_{LM} = \frac{V_{CS(TH)}}{R_S} 
\]

(10)

For a 5-V output, the maximum current sense signal occurs at the minimum input voltage, so \(R_S\) is calculated with Equation 11.

\[
R_S \leq \frac{V_{CS(TH)}}{I_O + \frac{V_{OUT}}{2L \times f_{SW}} \times \left(1 + \frac{V_{OUT}}{V_{IN(MIN)}}\right)} 
\]

(11)

For this example \(VCCX = 0\) V, so \(V_{CS(TH)} = 0.11\) V. The current sense resistor is calculated with Equation 12.

\[
R_S \leq \frac{0.11V}{7A \times \frac{5V}{2 \times 6 \mu H \times 250kHz} \times \left(1 + \frac{5V}{7V}\right)} \leq 0.011 \Omega
\]

(12)
The next lowest standard value of 10 mΩ was chosen for \( R_S \).

### 8.2.2.4 Ramp Capacitor

With the inductor and sense resistor value selected, the value of the ramp capacitor (\( C_{RAMP} \)) necessary for the emulation ramp circuit is **Equation 13**.

\[
C_{RAMP} \approx \frac{g_m \times L}{A 	imes R_S}
\]

where

- \( L \) is the value of the output inductor in Henrys
- \( g_m \) is the ramp generator transconductance (5 µA/V)
- \( A \) is the current sense amplifier gain (10 V/V)

**Equation 13**

For the 5-V output design example, the ramp capacitor is calculated with **Equation 14**.

\[
C_{RAMP} = \frac{5 \text{ µA/V} \times 6 \mu\text{H}}{10\text{V/V} \times 10 \text{ mΩ}} = 300 \text{ pF}
\]

**Equation 14**

The next lowest standard value of 270 pF was selected for \( C_{RAMP} \). A COG type capacitor with 5% or better tolerance is recommended.

### 8.2.2.5 Output Capacitors

The output capacitors smooth the inductor ripple current and provide a source of charge for transient loading conditions. For this design example, five 100-µF ceramic capacitors were selected. Ceramic capacitors provide very low equivalent series resistance (ESR), but can exhibit a significant reduction in capacitance with DC bias. From the manufacturer’s data, the ESR at 250 kHz is 2 mΩ / 5 = 0.4 mΩ, with a 36% reduction in capacitance at 5 V. This is verified by measuring the output ripple voltage and frequency response of the circuit. The fundamental component of the output ripple voltage is calculated with **Equation 15**.

\[
\Delta V_{OUT} = I_{FP} \times \sqrt{\text{ESR}^2 + \left( \frac{1}{8 \times f_{SW} \times C_{OUT}} \right)^2}
\]

**Equation 15**

**Equation 16** calculates the typical values for the 5-V design example.

\[
\Delta V_{OUT} = 3A \times \sqrt{0.4 \text{ mΩ}^2 + \left( \frac{1}{8 \times 250 \text{ kHz} \times 320 \mu\text{F}} \right)^2}
\]

\[
\Delta V_{OUT} = 4.8 \text{ mV}
\]

### 8.2.2.6 Input Capacitors

The regulator supply voltage has a large source impedance at the switching frequency. Good quality input capacitors are necessary to limit the ripple voltage at the VIN pin while supplying most of the switch current during the on-time. When the buck switch turns on, the current into the switch steps to the valley of the inductor current waveform, ramps up to the peak value, and then drops to zero at turnoff. The input capacitors must be selected for RMS current rating and minimum ripple voltage. A good approximation for the required ripple current rating is \( I_{RMS} > I_{OUT} / 2 \).

Quality ceramic capacitors with a low ESR were selected for the input filter. To allow for capacitor tolerances and voltage rating, four 2.2-µF ceramic capacitors were used for the typical application circuit. With ceramic capacitors, the input ripple voltage is triangular and peak at 50% duty cycle. Considering the capacitance change with DC bias, the input ripple voltage is approximated with **Equation 17**.

\[
\Delta V_{IN} = \frac{I_{OUT}}{4 \times f_{SW} \times C_{IN}} = \frac{7A}{4 \times 250 \text{ kHz} \times 7 \mu\text{F}} = 1V
\]

**Equation 17**

When the converter is connected to an input power source, a resonant circuit is formed by the line impedance and the input capacitors. If step input voltage transients are expected near the maximum rating of the LM25116, a careful evaluation of the ringing and possible overshoot at the device VIN pin must be completed. To minimize overshoot make \( C_{IN} > 10 \times L_{IN} \). The characteristic source impedance and resonant frequency are in **Equation 18**.
\[ Z_S = \frac{L_{IN}}{C_{IN}} \quad f_S = \frac{1}{2\pi \sqrt{L_{IN} \times C_{IN}}} \] (18)

The converter exhibits a negative input impedance which is lowest at the minimum input voltage in Equation 19.

\[ Z_{IN} = \frac{V_{IN}^2}{P_{OUT}} \] (19)

The damping factor for the input filter is given by Equation 20.

\[ \delta = 1 + \frac{R_{IN} + ESR \times Z_S}{Z_S + Z_{IN}} \]

where
- \( R_{IN} \) is the input wiring resistance
- \( ESR \) is the series resistance of the input capacitors

The term \( Z_S / Z_{IN} \) is always negative due to \( Z_{IN} \). When \( \delta = 1 \), the input filter is critically damped. This may be difficult to achieve with practical component values. With \( \delta < 0.2 \), the input filter exhibits significant ringing. If \( \delta \) is zero or negative, there is not enough resistance in the circuit and the input filter sustains an oscillation. When operating near the minimum input voltage, an aluminum electrolytic capacitor across \( C_{IN} \) may be required to damp the input for a typical bench test setup. Any parallel capacitor must be evaluated for its RMS current rating. The current splits between the ceramic and aluminum capacitors based on the relative impedance at the switching frequency.

8.2.2.7 VCC Capacitor

The primary purpose of the VCC capacitor (\( C_{VCC} \)) is to supply the peak transient currents of the LO driver and bootstrap diode (D1) as well as provide stability for the VCC regulator. These current peaks can be several amperes. The recommended value of \( C_{VCC} \) must be no smaller than 0.47 µF, and must be a good quality, low ESR, ceramic capacitor placed at the pins of the IC to minimize potentially damaging voltage transients caused by trace inductance. A value of 1 µF was selected for this design.

8.2.2.8 Bootstrap Capacitor

The bootstrap capacitor (\( C_{HB} \)) between the HB and SW pins supplies the gate current to charge the high-side MOSFET gate at the turnon of each cycle as well as supplying the recovery charge for the bootstrap diode (D1). These current peaks can be several amperes. The recommended value of the bootstrap capacitor is at least 0.1 µF, and must be a good quality, low ESR, ceramic capacitor placed at the pins of the IC to minimize potentially damaging voltage transients caused by trace inductance. The absolute minimum value for the bootstrap capacitor is calculated as:

\[ C_{HB} \geq \frac{Q_g}{\Delta V_{HB}} \] (21)

where
- \( Q_g \) is the high-side MOSFET gate charge
- \( \Delta V_{HB} \) is the tolerable voltage droop on \( C_{HB} \)

\( \Delta V_{HB} \) is typically less than 5% of VCC. A value of 1 µF was selected for this design.

8.2.2.9 Soft Start Capacitor

The capacitor at the SS pin (\( C_{SS} \)) determines the soft-start time, which is the time for the reference voltage and the output voltage to reach the final regulated value. The soft-start time \( t_{SS} \) must be substantially longer than the time required to charge \( C_{OUT} \) to \( V_{OUT} \) at the maximum output current. To meet this requirement, use Equation 22.

\[ t_{SS} > V_{OUT} \times C_{OUT} / (I_{CURRENT\ LIMIT} - I_{OUT}) \] (22)

The value of \( C_{SS} \) for a given time is determined with Equation 23.

\[ C_{SS} = \frac{t_{SS} \times 10 \text{ µA}}{1.215V} \] (23)

For this application, a value of 0.01 µF was chosen for a soft-start time of 1.2 ms.
8.2.2.10 **Output Voltage Divider**

\[ R_{FB1} \text{ and } R_{FB2} \text{ set the output voltage level, the ratio of these resistors is calculated with Equation 24.} \]

\[ \frac{R_{FB2}}{R_{FB1}} = \frac{V_{OUT} - 1}{1.215V} \]  

(24)

\[ R_{FB1} \text{ is typically } 1.21 \text{ k}\Omega \text{ for a divider current of } 1 \text{ mA. The divider current can be reduced to } 100 \mu\text{A with } R_{FB1} = 12.1 \text{ k}\Omega. \text{ For the 5-V output design example used here, } R_{FB1} = 1.21 \text{ k}\Omega \text{ and } R_{FB2} = 3.74 \text{ k}\Omega. \]

8.2.2.11 **UVLO Divider**

A voltage divider and filter can be connected to the UVLO pin to set a minimum operating voltage \( V_{IN(MIN)} \) for the regulator. If this feature is required, the following procedure is used to determine appropriate resistor values for \( R_{UV2}, R_{UV1} \) and \( C_{FT} \).

1. \( R_{UV2} \) must be large enough such that in the event of a current limit, the internal UVLO switch can pull UVLO < 200 mV. This can be ensured if:
   \[ R_{UV2} > 500 \times V_{IN(MAX)}, \]
   where \( V_{IN(MAX)} \) is the maximum input voltage and \( R_{UV2} \) is in ohms.

2. With an appropriate value for \( R_{UV2}, R_{UV1} \) can be selected using Equation 25.

\[ R_{UV1} = 1.215 \times \left( \frac{R_{UV2}}{V_{IN(MIN)} + (5 \mu A \times R_{UV2}) - 1.215} \right) \]

where

- \( V_{IN(MIN)} \) is the desired shutdown voltage

3. Capacitor \( C_{FT} \) provides filtering for the divider and determines the off-time of the 'hiccup' duty cycle during current limit. When \( C_{FT} \) is used in conjunction with the voltage divider, a diode across the top resistor must be used to discharge \( C_{FT} \) in the event of an input undervoltage condition in Equation 26.

\[ t_{OFF} = \left( \frac{R_{UV1} \times R_{UV2}}{R_{UV1} + R_{UV2}} \right) \times C_{FT} \times \ln \left( \frac{1.215 \times (R_{UV1} + R_{UV2})}{V_{IN} \times R_{UV1}} \right) \]

(26)

If undervoltage shutdown is not required, \( R_{UV1} \) and \( R_{UV2} \) can be eliminated and the off-time becomes Equation 27.

\[ t_{OFF} = C_{FT} \times \frac{1.215V}{5 \mu A} \]

(27)

The voltage at the UVLO pin must never exceed 16 V when using an external setpoint divider. It may be necessary to clamp the UVLO pin at high input voltages. For the design example, \( R_{UV2} = 102 \text{ k}\Omega \) and \( R_{UV1} = 21 \text{ k}\Omega \) for a shutdown voltage of 6.6 V. If sustained short-circuit protection is required, \( C_{FT} \geq 1 \mu\text{F} \) limits the short-circuit power dissipation. D2 may be installed when using \( C_{FT} \) with \( R_{UV1} \) and \( R_{UV2} \).

8.2.2.12 **MOSFETs**

Selection of the power MOSFETs is governed by the same tradeoffs as switching frequency. Breaking down the losses in the high-side and low-side MOSFETs is one way to determine relative efficiencies between different devices. When using discrete 8-pin SO MOSFETs, the LM25116 is most efficient for output currents of 2 A to 10 A. Losses in the power MOSFETs can be broken down into conduction loss, gate charging loss, and switching loss. Conduction, or I^2R loss \( P_{DC} \), is approximately Equation 28 and Equation 29.

\[ P_{DC(HO-MOSFET)} = D \times (I_o^2 \times R_{DS(ON)} \times 1.3) \]
\[ P_{DC(LO-MOSFET)} = (1 - D) \times (I_o^2 \times R_{DS(ON)} \times 1.3) \]

(28)

(29)

where

- \( D \) is the duty cycle

The factor 1.3 accounts for the increase in MOSFET on-resistance due to heating. Alternatively, the factor of 1.3 can be ignored and the on-resistance of the MOSFET can be estimated using the \( R_{DS(ON)} \) versus Temperature curves in the MOSFET datasheet. Gate charging loss, \( P_{GC} \), results from the current driving the gate capacitance of the power MOSFETs and is approximated with Equation 30.

\[ P_{GC} = n \times VCC \times Q_g \times f_{SW} \]

(30)
Q_g refers to the total gate charge of an individual MOSFET, and ‘n’ is the number of MOSFETs. If different types of MOSFETs are used, the ‘n’ term can be ignored and their gate charges summed to form a cumulative Q_g.

Gate charge loss differs from conduction and switching losses in that the actual dissipation occurs in the LM25116 and not in the MOSFET itself. Further loss in the LM25116 is incurred as the gate driving current is supplied by the internal linear regulator. The gate drive current supplied by the VCC regulator is calculated with Equation 31.

\[ I_{GC} = (Q_{gh} + Q_{gl}) \times f_{SW} \]

where

- Q_{gh} + Q_{gl} represent the gate charge of the HO and LO MOSFETs at VGS = VCC

To ensure start-up, I_{GC} must be less than the VCC current limit rating of 15 mA minimum when powered by the internal 7.4-V regulator. Failure to observe this rating may result in excessive MOSFET heating and potential damage. The I_{GC} run current may exceed 15 mA when VCC is powered by VCCX.

Switching loss occurs during the brief transition period as the MOSFET turns on and off. During the transition period both current and voltage are present in the channel of the MOSFET. The switching loss can be approximated with Equation 32.

\[ P_{SW} = 0.5 \times V_{IN} \times I_{O} \times (t_{R} + t_{F}) \times f_{SW} \]

where

- t_{R} and t_{F} are the rise and fall times of the MOSFET

Switching loss is calculated for the high-side MOSFET only. Switching loss in the low-side MOSFET is negligible because the body diode of the low-side MOSFET turns on before the MOSFET itself, minimizing the voltage from drain to source before turnon. For this example, the maximum drain-to-source voltage applied to either MOSFET is 42 V. VCC provides the drive voltage at the gate of the MOSFETs. The selected MOSFETs must be able to withstand 42 V plus any ringing from drain to source, and be able to handle at least VCC plus ringing from gate to source. A good choice of MOSFET for the 42-V input design example is the Si7850DP. It has an R_{DS(ON)} of 20 mΩ, total gate charge of 14 nC, and rise and fall times of 10 ns and 12 ns respectively. In applications where a high step-down ratio is maintained for normal operation, efficiency may be optimized by choosing a high-side MOSFET with lower Q_g, and low-side MOSFET with lower R_{DS(ON)}.

For higher voltage MOSFETs which are not true logic level, it is important to use the UVLO feature. Choose a minimum operating voltage which is high enough for VCC and the bootstrap (HB) supply to fully enhance the MOSFET gates. This prevents operation in the linear region during power-on or power-off which can result in MOSFET failure. Similar consideration must be made when powering VCCX from the output voltage. For the high-side MOSFET, the gate threshold must be considered and careful evaluation made if the gate threshold voltage exceeds the HO driver UVLO.

### 8.2.2.13 MOSFET Snubber

A resistor-capacitor snubber network across the low-side MOSFET reduces ringing and spikes at the switching node. Excessive ringing and spikes can cause erratic operation and couple spikes and noise to the output. Selecting the values for the snubber is best accomplished through empirical methods. First, make sure the lead lengths for the snubber connections are very short. Start with a resistor value between 5 Ω and 50 Ω. Increasing the value of the snubber capacitor results in more damping, but higher snubber losses. Select a minimum value for the snubber capacitor that provides adequate damping of the spikes on the switch waveform at high load.

### 8.2.2.14 Error Amplifier Compensation

R_{COMP}, C_{COMP} and C_{HC} configure the error amplifier gain characteristics to accomplish a stable voltage loop gain. One advantage of current mode control is the ability to close the loop with only two feedback components, R_{COMP} and C_{COMP}. The voltage loop gain is the product of the modulator gain and the error amplifier gain. For the 5-V output design example, the modulator is treated as an ideal voltage-to-current converter. The DC modulator gain of the LM25116 can be modeled with Equation 33.

\[ \text{DC Gain}_{(MOD)} = \frac{R_{LOAD}}{A \times R_{S}} \]  

The dominant low frequency pole of the modulator is determined by the load resistance (R_{LOAD}) and output capacitance (C_{OUT}). The corner frequency of this pole is calculated with Equation 34.

\[ f_{P(MOD)} = \frac{1}{(2\pi \times R_{LOAD} \times C_{OUT})} \]  

For R_{LOAD} = 5 V / 7 A = 0.714 Ω and C_{OUT} = 320 µF (effective) then f_{P(MOD)} = 700 Hz
DC Gain_{(MOD)} = 0.714 \, \Omega / (10 \times 10 \, \text{m\Omega}) = 7.14 = 17 \, \text{dB}

For the 5-V design example, the modulator gain versus frequency characteristic was measured as shown in Figure 35.

Components $R_{\text{COMP}}$ and $C_{\text{COMP}}$ configure the error amplifier as a type II configuration. The DC gain of the amplifier is 80 dB which has a pole at low frequency and a zero at $f_{\text{ZEA}} = 1 / (2\pi \times R_{\text{COMP}} \times C_{\text{COMP}})$. The error amplifier zero cancels the modulator pole leaving a single pole response at the crossover frequency of the voltage loop. A single pole response at the crossover frequency yields a very stable loop with 90° of phase margin. For the design example, a target loop bandwidth (crossover frequency) of one-tenth the switching frequency or 25 kHz was selected. The compensation network zero ($f_{\text{ZEA}}$) must be selected at least an order of magnitude less than the target crossover frequency. This constrains the product of $R_{\text{COMP}}$ and $C_{\text{COMP}}$ for a desired compensation network zero $1 / (2\pi \times R_{\text{COMP}} \times C_{\text{COMP}})$ to be 2.5 kHz. Increasing $R_{\text{COMP}}$, while proportionally decreasing $C_{\text{COMP}}$, increases the error amp gain. Conversely, decreasing $R_{\text{COMP}}$ while proportionally increasing $C_{\text{COMP}}$, decreases the error amp gain. For the design example, $C_{\text{COMP}}$ was selected as 3300 pF and $R_{\text{COMP}}$ was selected as 18 k\Omega. These values configure the compensation network zero at 2.7 kHz. The error amp gain at frequencies greater than $f_{\text{ZEA}}$ is: $R_{\text{COMP}} / R_{\text{FB2}}$, which is approximately 4.8 (13.6 dB).
The overall voltage loop gain can be predicted as the sum (in dB) of the modulator gain and the error amp gain.

If a network analyzer is available, the modulator gain can be measured and the error amplifier gain can be configured for the desired loop transfer function. If a network analyzer is not available, the error amplifier compensation components can be designed with the guidelines given. Step load transient tests can be performed to verify acceptable performance. The step load goal is minimum overshoot with a damped response. \( C_{HF} \) can be added to the compensation network to decrease noise susceptibility of the error amplifier. The value of \( C_{HF} \) must be sufficiently small because the addition of this capacitor adds a pole in the error amplifier transfer function. This pole must be well beyond the loop crossover frequency. A good approximation of the location of the pole added by \( C_{HF} \) is: \( f_p = f_{ZEA} \times C_{COMP} / C_{HF} \). The value of \( C_{HF} \) was selected as 100 pF for the design example.

### 8.2.2.15 Comprehensive Equations

#### 8.2.2.15.1 Current Sense Resistor and Ramp Capacitor

\( T = 1 / f_{SW}, \ g_m = 5 \mu A/V, \ A = 10 V/V. \ I_{OUT} \) is the maximum output current at current limit.

General method for \( V_{OUT} < 5 \) V is Equation 35 and Equation 36.

\[
R_s = \frac{V_{CS(TH)}}{I_{OUT}} \cdot \frac{V_{OUT} \times T}{2 \times L} \times \left(1 - \frac{V_{OUT}}{V_{IN(MIN)}}\right) + \frac{V_{OUT} \times T}{L} \times \left(1 + \frac{5 \cdot V_{OUT}}{V_{IN(MIN)}}\right)
\]

\[
C_{RAMP} = \frac{g_m \times L}{A \times R_s} \times \left(1 + \frac{5 \cdot V_{OUT}}{V_{IN(MAX)}}\right)
\]

(35) (36)

General method for \( 5 \) V < \( V_{OUT} < 7.5 \) V is Equation 37 and Equation 38.

\[
R_s = \frac{V_{CS(TH)}}{I_{OUT}} \cdot \frac{V_{OUT} \times T}{2 \times L} \times \left(1 - \frac{V_{OUT}}{V_{IN(MIN)}}\right) + \frac{V_{OUT} \times T}{L}
\]

\[
C_{RAMP} = \frac{g_m \times L}{A \times R_s} \times \left(1 + \frac{5 \cdot V_{OUT}}{V_{IN(MIN)}}\right)
\]

(37) (38)
Best performance method minimizes the current limit deviation due to changes in line voltage, while maintaining near optimal slope compensation.

Calculate optimal slope current with Equation 39, \( I_{OS} = \frac{\text{V}_{OUT}}{3} \times 10 \text{ µA/V} \). For example, at \( \text{V}_{OUT} = 7.5 \text{ V} \), \( I_{OS} = 25 \text{ µA} \).

\[
R_S = \frac{\text{V}_{CS(TH)}}{I_{OUT} + \frac{\text{V}_{OUT}}{L}} \quad C_{RAMP} = \frac{I_{OS} \times L}{\text{V}_{OUT} \times A \times R_S}
\]

(39)

Calculate \( V_{RAMP} \) at the nominal input voltage with Equation 40.

\[
V_{RAMP} = \frac{\text{V}_{OUT}}{V_{IN}} \times \frac{(V_{IN} - V_{OUT}) \times g_m + I_{OS} \times T}{C_{RAMP}}
\]

(40)

For \( V_{OUT} > 7.5 \text{ V} \), install a resistor from the RAMP pin to VCC and calculate with Equation 41.

\[
R_{RAMP} = \frac{\text{VCC} - V_{RAMP}}{I_{OS} - 25 \text{ µA}}
\]

(41)

Figure 38. \( R_{RAMP} \) to VCC for \( V_{OUT} > 7.5 \text{ V} \)

For \( V_{OUT} < 7.5 \text{ V} \), a negative VCC is required. This can be made with a simple charge pump from the LO gate output. Install a resistor from the RAMP pin to the negative VCC and calculate with Equation 42.

\[
R_{RAMP} = \frac{\text{VCC} - 0.5V + V_{RAMP}}{25 \text{ µA} - I_{OS}}
\]

(42)

Figure 39. \( R_{RAMP} \) to –VCC for \( V_{OUT} < 7.5 \text{ V} \)

If a large variation is expected in VCC, say for \( V_{IN} < 11 \text{ V} \), a Zener regulator may be added to supply a constant voltage for \( R_{RAMP} \).

8.2.2.15.2 Modulator Transfer Function

Equation 43 through Equation 47 can be used to calculate the control-to-output transfer function.

\[
\frac{\text{V}_{OUT}}{\text{V}_{COMP}} = \frac{R_{LOAD}}{A \times R_S} \times \frac{1}{1 + \frac{R_{LOAD}}{K_m \times A \times R_S} \left(1 + \frac{s}{\omega_P} \right) \left(1 + \frac{s}{\omega_N} \right) \left(1 + \frac{s^2}{\omega_n^2} \right)}
\]

(43)

\[
K_m = \frac{1}{\frac{(D - 0.5) \times A \times R_S \times T}{L} + (1 - 2 \times D) \times K_{SL} + \frac{V_{SL}}{V_{IN}}}
\]

(44)
\[
K_{SL} = \frac{g_m \times T}{C_{RAMP}} \quad V_{SL} = \frac{I_{OS} \times T}{C_{RAMP}}
\]
\[
\omega_{Z} = \frac{1}{C_{OUT} \times ESR} \quad \omega_{p} = \frac{1}{C_{OUT} \times \left(1 + \frac{K_{m} \times A \times R_s}{R_{LOAD}}\right)} \quad \omega_n = \frac{\pi}{T}
\]
\[
S_n = \frac{V_{IN} - V_{OUT}}{L} + K_{SL} + V_{SL} \quad m_c = \frac{S_n}{S_m} \quad Q = \frac{1}{\pi \times (m_c - 0.5)}
\]

K\textsubscript{m} is the effective DC gain of the modulating comparator. The duty cycle \(D = \frac{V_{OUT}}{V_{IN}}\). \(K_{SL}\) is the proportional slope compensation term. \(V_{SL}\) is the fixed slope compensation term. \(m_c\) is the ratio of the external ramp to the natural ramp. The switching frequency sampling gain is characterized by \(\omega_n\) and \(Q\), which accounts for the high frequency inductor pole.

For \(V_{SL}\) without \(R_{RAMP}\), use \(I_{OS} = 25 \, \mu A\).

For \(V_{SL}\) with \(R_{RAMP}\) to \(V_{CC}\), use \(I_{OS} = 25 \, \mu A + V_{CC}/R_{RAMP}\).

For \(V_{SL}\) with \(R_{RAMP}\) to \(-V_{CC}\), use \(I_{OS} = 25 \, \mu A - V_{CC}/R_{RAMP}\).

### 8.2.2.15.3 Error Amplifier Transfer Function

Equation 48, Equation 49, and Equation 50 are used to calculate the error amplifier transfer function:

\[
\frac{V_{COMP}}{V_{OUT(FB)}} = G_{EA(S)} \times \frac{1}{1 + \left(\frac{1}{A_{OL}} + \frac{s}{\omega_{BW}}\right) \times \left(1 + \frac{G_{EA(S)}}{K_{FB}}\right)}
\]

\[
G_{EA(S)} = \frac{1 + \frac{s}{\omega_{EA}}}{\omega_{EA} x \left(1 + \frac{s}{\omega_{BF}}\right)} \quad K_{FB} = \frac{R_{FB1}}{R_{FB1} + R_{FB2}}
\]

\[
\omega_{EA} = \frac{1}{C_{COMP} \times R_{COMP}} \quad \omega_{O} = \frac{1}{(C_{HF} + C_{COMP}) \times R_{FB2}}
\]

\[
\omega_{HF} = \frac{(C_{HF} + C_{COMP})}{C_{HF} \times C_{COMP} \times R_{COMP}}
\]

where

- \(A_{OL} = 10,000\) (80 dB)
- \(\omega_{BW} = 2\pi \times f_{BW}\)
- \(G_{EA(S)}\) is the ideal error amplifier gain, which is modified at DC and high frequency by the open loop gain of the amplifier and the feedback divider ratio.
9 Power Supply Recommendations

The LM25116 is a power management device. The power supply for the device is any DC voltage.

10 Layout

10.1 Layout Guidelines

In a buck regulator the primary switching loop consists of the input capacitor, MOSFETs and current sense resistor. Minimizing the area of this loop reduces the stray inductance and minimizes noise and possible erratic operation. The input capacitor must be placed as close as possible to the MOSFETs, with the VIN side of the capacitor connected directly to the high-side MOSFET drain, and the GND side of the capacitor connected as close as possible to the low-side source or current sense resistor ground connection. A ground plane in the PC board is recommended as a means to connect the quiet end (input voltage ground side) of the input filter capacitors to the output filter capacitors and the PGND pin of the regulator. Connect all of the low power ground connections (C_SS, R_T, C_RAMP) directly to the regulator AGND pin. Connect the AGND and PGND pins together through to a topside copper area covering the entire underside of the device. Place several vias in this underside copper area to the ground plane.

The highest power dissipating components are the two power MOSFETs. The easiest way to determine the power dissipated in the MOSFETs is to measure the total conversion losses (P_{IN} – P_{OUT}), then subtract the power losses in the output inductor and any snubber resistors. The resulting power losses are primarily in the switching MOSFETs.

If a snubber is used, the power loss can be estimated with an oscilloscope by observation of the resistor voltage drop at both turnon and turnoff transitions. Assuming that the RC time constant is ≤ 1 / f_{SW},

\[ P = C \times V^2 \times f_{SW} \]  

(51)

The regulator has an exposed thermal pad to aid power dissipation. Selecting MOSFETs with exposed pads aid the power dissipation of these devices. Careful attention to R_{DSON} at high temperature must be observed. Also, at 250 kHz, a MOSFET with low gate capacitance result in lower switching losses.
10.2 Layout Example

Place controller as close to the switches.

(1) The marketing status values are defined as follows:
- **ACTIVE**: Product device recommended for new designs.
- **LIFEBUY**: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
- **NRND**: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.
- **PREVIEW**: Device has been announced but is not in production. Samples may or may not be available.
- **OBSOLETE**: TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check [http://www.ti.com/productcontent](http://www.ti.com/productcontent) for the latest availability information and additional product content details.
- **TBD**: The Pb-Free/Green conversion plan has not been defined.
- **Pb-Free (RoHS)**: TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.
- **Pb-Free (RoHS Exempt)**: This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.
- **Green (RoHS & no Sb/Br)**: TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.
