

PCA9546A 低電圧 4 チャンネル I²C および SMBus スイッチ (リセット機能付き)

1 特長

- 1 対 4 の双方向変換スイッチ
- I²C バスおよび SMBus 互換
- アクティブ LOW のリセット入力
- 3 本のアドレス・ピンにより、最大 8 個の PCA9546A を I²C バスに接続可能
- I²C バス経由で、任意の組み合わせのチャンネルを選択可能
- 電源オン時は、すべてのスイッチ・チャンネルが選択解除された状態
- 低い R_{ON} のスイッチ
- 1.8V、2.5V、3.3V、5V の各電圧のバス間での電圧レベル変換
- 電源オン時のグリッチなし
- 活線挿抜をサポート
- 低スタンバイ電流
- 2.3V～5.5V の動作電源電圧範囲
- 5.5V 許容の入力
- 0～400kHz のクロック周波数
- JESD 78 準拠で 100mA 超のラッチアップ性能
- JESD 22 を超える ESD 保護
 - 2000V、人体モデル (A114-A)
 - 1000V、荷電デバイス・モデル (C101)

2 アプリケーション

- サーバー
- ルーター (テレコム・スイッチング機器)
- ファクトリ・オートメーション
- I²C スレーブ・アドレス競合がある製品 (複数の同一温度センサなど)

3 概要

PCA9546A は、I²C バスで制御されるクワッド双方向変換スイッチです。SCL/SDA 上流ペアが、4 つの下流ペア (チャンネル) に展開されます。プログラム可能な制御レジスタの設定により、どのような個別の SCn/SDn チャンネルでも、あるいは、チャンネルの組み合わせでも選択できます。

アクティブ LOW のリセット入力 ($\overline{\text{RESET}}$) により、PCA9546A は下流の I²C バスの 1 つが LOW 状態に固着した状況から回復できます。 $\overline{\text{RESET}}$ を LOW にすると、I²C ステート・マシンがリセットされ、すべてのチャンネルが選択解除されます (内部のパワー・オン・リセット機能と同様)。

スイッチのパス・ゲートは、PCA9546A から印加される最大の HIGH 電圧を、V_{CC} ピンを使用して制限できるように構成されています。これによって、ペアごとに異なるバス電圧を使用できるため、1.8V、2.5V、3.3V の部品が、追加保護の必要なしに 5V の部品と通信を行えます。外付けのプルアップ抵抗により、各チャンネルに求められる電圧レベルにバスをプルアップします。すべての I/O ピンは 5.5V 許容です。

8 Detailed Description

8.1 Overview

The PCA9546A is a 4-channel, bidirectional translating I²C switch. The master SCL/SDA signal pair is directed to four channels of slave devices, SC0/SD0-SC3/SD3. Any individual downstream channel can be selected as well as any combination of the four channels.

The device offers an active-low $\overline{\text{RESET}}$ input which resets the state machine and allows the PCA9546A to recover should one of the downstream I²C buses get stuck in a low state. The state machine of the device can also be reset by cycling the power supply, V_{CC} , also known as a power-on reset (POR). Both the $\overline{\text{RESET}}$ function and a POR will cause all channels to be deselected.

The connections of the I²C data path are controlled by the same I²C master device that is switched to communicate with multiple I²C slaves. After the successful acknowledgment of the slave address (hardware selectable by A0 and A1 pins), a single 8-bit control register is written to or read from to determine the selected channels.

The PCA9546A may also be used for voltage translation, allowing the use of different bus voltages on each SCn/SDn pair such that 1.8-V, 2.5-V, or 3.3-V parts can communicate with 5-V parts. This is achieved by using external pull-up resistors to pull the bus up to the desired voltage for the master and each slave channel.

8.3 Feature Description

The PCA9546A is a 4-channel, bidirectional translating switch for I²C buses that supports Standard-Mode (100 kHz) and Fast-Mode (400 kHz) operation. The PCA9546A features I²C control using a single 8-bit control register in which the four least significant bits control the enabling and disabling of the 4 switch channels of I²C data flow. Depending on the application, voltage translation of the I²C bus can also be achieved using the PCA9546A to allow 1.8-V, 2.5-V, or 3.3-V parts to communicate with 5-V parts. Additionally, in the event that communication on the I²C bus enters a fault state, the PCA9546A can be reset to resume normal operation using the RESET pin feature or by a power-on reset which results from cycling power to the device.

8.4 Device Functional Modes

8.4.1 RESET Input

The RESET input is an active-low signal that may be used to recover from a bus-fault condition. When this signal is asserted low for a minimum of t_{WL} , the PCA9546A resets its registers and I²C state machine and deselects all channels. The RESET input must be connected to V_{CC} through a pull-up resistor.

8.4.1.1 RESET Errata

If RESET voltage set higher than V_{CC}, current will flow from RESET pin to V_{CC} pin.

System Impact

V_{CC} will be pulled above its regular voltage level

System Workaround

Design such that RESET voltage is same or lower than V_{CC}

8.4.2 Power-On Reset

When power is applied to V_{CC}, an internal power-on reset holds the PCA9546A in a reset condition until V_{CC} has reached V_{POR}. At this point, the reset condition is released, and the PCA9546A registers and I²C state machine are initialized to their default states, all zeroes, causing all the channels to be deselected. Thereafter, V_{CC} must be lowered below V_{POR} to reset the device.

8.5 Programming

8.5.1 I²C Interface

The I²C bus is for two-way two-line communication between different ICs or modules. The two lines are a serial data line (SDA) and a serial clock line (SCL). Both lines must be connected to a positive supply via a pull-up resistor when connected to the output stages of a device. Data transfer can be initiated only when the bus is not busy.

One data bit is transferred during each clock pulse. The data on the SDA line must remain stable during the high period of the clock pulse, as changes in the data line at this time are interpreted as control signals (see [Figure 8-1](#)).

Figure 8-1. Bit Transfer

Both data and clock lines remain high when the bus is not busy. A high-to-low transition of the data line while the clock is high is defined as the start condition (S). A low-to-high transition of the data line while the clock is high is defined as the stop condition (P) (see [Figure 8-2](#)).

Figure 8-2. Definition of Start and Stop Conditions

A device generating a message is a transmitter; a device receiving is the receiver. The device that controls the message is the master, and the devices that are controlled by the master are the slaves (see [Figure 8-3](#)).

Figure 8-3. System Configuration

The number of data bytes transferred between the start and the stop conditions from transmitter to receiver is not limited. Each byte of eight bits is followed by one acknowledge (ACK) bit. The transmitter must release the SDA line before the receiver can send an ACK bit.

When a slave receiver is addressed, it must generate an ACK after the reception of each byte. Also, a master must generate an ACK after the reception of each byte that has been clocked out of the slave transmitter. The device that acknowledges must pull down the SDA line during the ACK clock pulse so that the SDA line is stable low during the high pulse of the ACK-related clock period (see [Figure 8-4](#)). Setup and hold times must be taken into account.

8-4. Acknowledgment on the I²C Bus

Data is transmitted to the PCA9546A control register using the write mode shown in 8-5.

8-5. Write Control Register

Data is read from the PCA9546A control register using the read mode shown in 8-6.

8-6. Read Control Register

8.6 Control Register

8.6.1 Device Address

Following a start condition, the bus master must output the address of the slave it is accessing. The address of the PCA9546A is shown in [Figure 8-7](#). To conserve power, no internal pull-up resistors are incorporated on the hardware-selectable address pins, and they must be pulled high or low.

Figure 8-7. PCA9546A Address

The last bit of the slave address defines the operation to be performed. When set to a logic 1, a read is selected, while a logic 0 selects a write operation.

8.6.2 Control Register Description

Following the successful acknowledgment of the slave address, the bus master sends a byte to the PCA9546A, which is stored in the control register (see [Figure 8-8](#)). If multiple bytes are received by the PCA9546A, it will save the last byte received. This register can be written and read via the I²C bus.

Figure 8-8. Control Register

8.6.3 Control Register Definition

One or several SCn/SDn downstream pairs, or channels, are selected by the contents of the control register (see [Table 8-1](#)). This register is written after the PCA9546A has been addressed. The four LSBs of the control byte are used to determine which channel or channels are to be selected. When a channel is selected, the channel becomes active after a stop condition has been placed on the I²C bus. This ensures that all SCn/SDn lines are in a high state when the channel is made active, so that no false conditions are generated at the time of connection. A stop condition always must occur right after the acknowledge cycle.

表 8-1. Control Register Write (Channel Selection), Control Register Read (Channel Status)⁽¹⁾

- (1) Several channels can be enabled at the same time. For example, B3 = 0, B2 = 1, B1 = 1, B0 = 0 means that channels 0 and 3 are disabled, and channels 1 and 2 are enabled. Care must be taken not to exceed the maximum bus capacity.

9.1 Application Information

Applications of the PCA9546A will contain an I²C (or SMBus) master device and up to four I²C slave devices. The downstream channels are ideally used to resolve I²C slave address conflicts. For example, if four identical digital temperature sensors are needed in the application, one sensor can be connected at each channel: 0, 1, 2, and 3. When the temperature at a specific location must be read, the appropriate channel can be enabled and all other channels switched off, the data can be retrieved, and the I²C master can move on and read the next channel.

In an application where the I²C bus will contain many additional slave devices that do not result in I²C slave address conflicts, these slave devices can be connected to any desired channel to distribute the total bus capacitance across multiple channels. If multiple switches will be enabled simultaneously, additional design requirements must be considered (See [Design Requirements](#) and [Detailed Design Procedure](#)).

9.2 Typical Application

A typical application of the PCA9546A will contain anywhere from 1 to 5 separate data pull-up voltages, V_{DPUX} , one for the master device (V_{DPU0}) and one for each of the selectable slave channels ($V_{DPU0} - V_{DPU3}$). In the event where the master device and all slave devices operate at the same voltage, then the pass voltage, $V_{PASS} = V_{DPUX}$. Once the maximum V_{PASS} is known, V_{CC} can be selected easily using [Figure 9-2](#). In an application where voltage translation is necessary, additional design requirements must be considered (See [Design Requirements](#)).

[Figure 9-1](#) shows an application in which the PCA9546A can be used.

Figure 9-1. PCA9546A Typical Application Schematic

9.2.1 Design Requirements

The A0, A1, and A2 pins are hardware selectable to control the slave address of the PCA9546A. These pins may be tied directly to GND or V_{CC} in the application.

If multiple slave channels will be activated simultaneously in the application, then the total I_{OL} from SCL/SDA to GND on the master side will be the sum of the currents through all pull-up resistors, R_p .

The pass-gate transistors of the PCA9546A are constructed such that the V_{CC} voltage can be used to limit the maximum voltage that is passed from one I²C bus to another.

✎ 9-2 shows the voltage characteristics of the pass-gate transistors (note that the graph was generated using data specified in the [Electrical Characteristics](#) section of this data sheet). In order for the PCA9546A to act as a voltage translator, the V_{pass} voltage must be equal to or lower than the lowest bus voltage. For example, if the main bus is running at 5 V and the downstream buses are 3.3 V and 2.7 V, V_{pass} must be equal to or below 2.7 V to effectively clamp the downstream bus voltages. As shown in ✎ 9-2, $V_{pass(max)}$ is 2.7 V when the PCA9546A supply voltage is 4 V or lower, so the PCA9546A supply voltage could be set to 3.3 V. Pull-up resistors then can be used to bring the bus voltages to their appropriate levels (see ✎ 9-1).

9.2.2 Detailed Design Procedure

Once all the slaves are assigned to the appropriate slave channels and bus voltages are identified, the pull-up resistors, R_p , for each of the buses need to be selected appropriately. The minimum pull-up resistance is a function of V_{DPUX} , $V_{OL(max)}$, and I_{OL} as shown in 式 1:

$$R_{p(min)} = \frac{V_{DPUX} - V_{OL(max)}}{I_{OL}} \quad (1)$$

The maximum pull-up resistance is a function of the maximum rise time, t_r (300 ns for fast-mode operation, f_{SCL} = 400 kHz) and bus capacitance, C_b as shown in 式 2:

$$R_{p(max)} = \frac{t_r}{0.8473 \times C_b} \quad (2)$$

The maximum bus capacitance for an I²C bus must not exceed 400 pF for fast-mode operation. The bus capacitance can be approximated by adding the capacitance of the PCA9546A, $C_{iO(OFF)}$, the capacitance of wires/connections/traces, and the capacitance of each individual slave on a given channel. If multiple channels will be activated simultaneously, each of the slaves on all channels will contribute to total bus capacitance.

9.2.3 Application Curves

9-2. Pass-Gate Voltage (V_{pass}) vs Supply Voltage (V_{CC}) at Three Temperature Points

Standard-mode ($f_{SCL} = 100$ kHz, $t_r = 1$ μ s)
 Fast-mode ($f_{SCL} = 400$ kHz, $t_r = 300$ ns)

9-3. Maximum Pull-Up resistance ($R_{p(max)}$) vs Bus Capacitance (C_b)

$V_{OL} = 0.2 \cdot V_{DPUX}$, $I_{OL} = 2$ mA when $V_{DPUX} \leq 2$ V

$V_{OL} = 0.4$ V, $I_{OL} = 3$ mA when $V_{DPUX} > 2$ V

9-4. Minimum Pull-Up Resistance ($R_{p(min)}$) vs Pull-Up Reference Voltage (V_{DPUX})

10 Power Supply Recommendations

10.1 Power-On Reset Requirements

In the event of a glitch or data corruption, PCA9546A can be reset to its default conditions by using the power-on reset feature. Power-on reset requires that the device go through a power cycle to be completely reset. This reset also happens when the device is powered on for the first time in an application.

The two types of power-on reset are shown in 10-1 and 10-2.

10-1. V_{CC} Is Lowered Below 0.2 V Or 0 V And Then Ramped Up To V_{CC}

10-2. V_{CC} Is Lowered Below The Por Threshold, Then Ramped Back Up To V_{CC}

表 10-1 specifies the performance of the power-on reset feature for PCA9546A for both types of power-on reset.

表 10-1. Recommended Supply Sequencing And Ramp Rates⁽¹⁾

PARAMETER			MIN	TYP	MAX	UNIT
V_{CC_FT}	Fall rate	See 10-1	1		100	ms
V_{CC_RT}	Rise rate	See 10-1	0.01		100	ms
$V_{CC_TRR_GND}$	Time to re-ramp (when V_{CC} drops to GND)	See 10-1	0.001			ms
$V_{CC_TRR_POR50}$	Time to re-ramp (when V_{CC} drops to $V_{POR_MIN} - 50$ mV)	See 10-2	0.001			ms
V_{CC_GH}	Level that V_{CCP} can glitch down to, but not cause a functional disruption when $V_{CCX_GW} = 1$ μ s	See 10-3			1.2	V
V_{CC_GW}	Glitch width that will not cause a functional disruption when $V_{CCX_GH} = 0.5 \times V_{CCX}$	See 10-3				μ s
V_{PORF}	Voltage trip point of POR on falling V_{CC}		0.767		1.144	V
V_{PORR}	Voltage trip point of POR on rising V_{CC}		1.033		1.428	V

(1) $T_A = -40^\circ\text{C}$ to 85°C (unless otherwise noted)

Glitches in the power supply can also affect the power-on reset performance of this device. The glitch width (V_{CC_GW}) and height (V_{CC_GH}) are dependent on each other. The bypass capacitance, source impedance, and the device impedance are factors that affect power-on reset performance. 10-3 and 表 10-1 provide more information on how to measure these specifications.

FIG 10-3. Glitch Width And Glitch Height

V_{POR} is critical to the power-on reset. V_{POR} is the voltage level at which the reset condition is released and all the registers and the I²C/SMBus state machine are initialized to their default states. The value of V_{POR} differs based on the V_{CC} being lowered to or from 0. FIG 10-4 and Table 10-1 provide more details on this specification.

FIG 10-4. V_{POR}

11 Layout

11.1 Layout Guidelines

For PCB layout of the PCA9546A, common PCB layout practices must be followed but additional concerns related to high-speed data transfer such as matched impedances and differential pairs are not a concern for I²C signal speeds. It is common to have a dedicated ground plane on an inner layer of the board and pins that are connected to ground must have a low-impedance path to the ground plane in the form of wide polygon pours and multiple vias. By-pass and de-coupling capacitors are commonly used to control the voltage on the V_{CC} pin, using a larger capacitor to provide additional power in the event of a short power supply glitch and a smaller capacitor to filter out high-frequency ripple.

In an application where voltage translation is not required, all V_{DPUX} voltages and V_{CC} could be at the same potential and a single copper plane could connect all of pull-up resistors to the appropriate reference voltage. In an application where voltage translation is required, V_{DPUM}, V_{DPU0}, V_{DPU1}, V_{DPU2}, and V_{DPU3} may all be on the same layer of the board with split planes to isolate different voltage potentials.

To reduce the total I²C bus capacitance added by PCB parasitics, data lines (SC_n and SD_n) must be as short as possible and the widths of the traces must also be minimized (e.g. 5-10 mils depending on copper weight).

12.4 Electrostatic Discharge Caution

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

⁽¹⁾ **Status:** For more details on status, see our [product life cycle](#).

⁽²⁾ **Material type:** When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

⁽³⁾ **RoHS values:** Yes, No, RoHS Exempt. See the [TI RoHS Statement](#) for additional information and value definition.

⁽⁴⁾ **Lead finish/Ball material:** Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

⁽⁵⁾ **MSL rating/Peak reflow:** The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

⁽⁶⁾ **Part marking:** There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

THERMAL INFORMATION

This package incorporates an exposed thermal pad that is designed to be attached directly to an external heatsink. The thermal pad must be soldered directly to the printed circuit board (PCB). After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For information on the Quad Flatpack No-Lead (QFN) package and its advantages, refer to Application Report, QFN/SON PCB Attachment, Texas Instruments Literature No. SLUA271. This document is available at www.ti.com.
