

TPS7A63-Q1、TPS7A6401-Q1

超低 I_Q 、300mA、40V、低ドロップアウト・レギュレータ

1 特長

- 車載アプリケーション用に AEC-Q100 認定取得済み
 - 温度グレード 1: $-40^{\circ}\text{C} \sim 125^{\circ}\text{C}$ 、 T_A
 - 接合部温度: $-40^{\circ}\text{C} \sim 150^{\circ}\text{C}$ 、 T_J
- 低いドロップアウト電圧:
 - $I_{OUT} = 150\text{mA}$ で 300mV
- $7\text{V} \sim 40\text{V}$ の広い入力電圧範囲、最大 45V の過電圧に対応
- 最大出力電流: 300mA
- 非常に低い静止電流
 - 軽負荷時に $I_{QUIESCENT} = 35\mu\text{A}$ (標準値)
 - $\text{EN} = \text{LOW}$ のとき $I_{SLEEP} < 2\mu\text{A}$
- 固定 (3.3V および 5V) および可変 ($2.5\text{V} \sim 7\text{V}$) の出力電圧
- フォルト / フラグ付きのウォッチドッグを内蔵
- 低 ESR のセラミック出力コンデンサで安定動作
- パワーオン・リセット機能を搭載
 - 遅延をプログラム可能
 - オープン・ドレイン・リセット出力
- フォルト保護機能を搭載
 - 短絡保護と過電流保護
 - サーマル・シャットダウン
- 低入力電圧トラッキング
- 熱的に強化された 14 ピンの HTSSOP-PWP パッケージと 10 ピンの VSON-DRK パッケージ

2 アプリケーション

- 車載用ヘッド・ユニット
- ヘッドライト
- DC/DC コンバータ
- 車載センター情報ディスプレイ

3 概要

TPS7A63-Q1およびTPS7A6401-Q1は、低ドロップアウトのリニア電圧レギュレータのファミリで、消費電力が低く、軽負荷アプリケーションで静止電流が $35\mu\text{A}$ 未満に設計されています。これらのデバイスは、低ESRのセラミック出力コンデンサでも安定して動作するよう設計されており、プログラム可能なウィンドウ・ウォッチドッグと過電流保護機能が搭載されています。設計者は、外付け抵抗を使用して出力電圧をプログラムできます。低電圧トラッキング機能により、小型の入力コンデンサを使用でき、コールド・クランク状況では多くの場合に昇圧コンバータが不要になります。パワー・オン・リセット遅延は固定(標準値 $250\mu\text{s}$)で、外付けコンデンサにより遅延をプログラムできます。これらの特長から、これらのデバイスは各種の車載アプリケーション用の電源に最適です。

Pin Functions

PIN			I/O	DESCRIPTION
NAME	PWP	DRK		
EN	5	4	I	Chip enable pin: This is a high-voltage-tolerant input pin with an internal pulldown. A high input to this pin activates the device and turns the regulator ON. Connect this input to the VIN terminal for self-bias applications. If this pin remains unconnected, the device stays disabled.
FB	3	—	I	Feedback pin (only applicable for TPS7A6x01-Q1): Sense voltage for error amplifier
GND	4	3	I/O	Ground pin: This is signal ground pin of the device.
NC	3	—	—	Not connected (only applicable for TPS7A6333-Q1 and TPS7A6350-Q1)
NC	8	—	—	Not connected
NC	11	—	—	Not connected
NC	13	—	—	Not connected
nRST	2	2	O	Reset pin: This is an open-drain reset output pin with an external pullup resistor connected to the VOUT pin.
nWD_EN	12	9	I	Watchdog enable pin: A high input to this pin disables the watchdog, and vice versa. This is an active-low input pin with an internal pulldown. Leaving this pin is unconnected and floating keeps the watchdog enabled. An external microcontroller can pull this pin high momentarily to disable and reinitialize the watchdog.
RDELAY	6	8	O	Reset delay timer pin: This pin programs the reset delay timer using an external capacitor (C_{DLY}) to ground.
ROSC	14	10	O	ROscillator pin: This pin programs the internal oscillator frequency (and hence the duration of the watchdog window) by connecting an external resistor to ground.
WD	10	7	I	Watchdog service pin: This is an input pin to provide a service signal to the watchdog.
WD_FLAG	9	6	O	Watchdog flag pin (for TPS7A6401-Q1 only): This is an active-high latched fault (that is, flag) output pin with an external pullup resistor connected to VOUT pin.
WD_FLT	9	6	O	Watchdog fault pin (for TPS7A63-Q1 only): This is an active-low fault output pin with an external pullup resistor connected to the VOUT pin.
VIN	1	1	I	Input voltage pin: The unregulated input voltage is supplied to this pin. A bypass capacitor connected between the VIN pin and GND pin dampens line transients on the input.
VOUT	7	5	O	Regulated output voltage pin: This is a regulated voltage output ($V_{OUT} = 3.3\text{ V}$ or 5 V or a programmed value) pin with a limitation on maximum output current. For devices with adjustable output voltage (TPS7A6x01-Q1), connecting an external resistor network programs the output voltage. In order to achieve stable operation and prevent oscillation, connect an external output capacitor (C_{OUT}) with low ESR between this pin and GND pin.

7 Detailed Description

7.1 Overview

The TPS7A63-Q1 and TPS7A6401-Q1 are a family of monolithic low-dropout linear voltage regulators with integrated watchdog and reset functionality. These voltage regulators are designed for low power consumption and quiescent current less than 25 μ A in light-load applications. Because of a programmable reset delay (also called power-on-reset delay), these devices are well-suited in power supplies for microprocessors and microcontrollers.

These devices are available in two fixed and adjustable output-voltage versions as follows:

- Fault (WD_FLT) output version: TPS7A63-Q1
- Flag (WD_FLAG) output version: TPS7A6401-Q1

[Feature Description](#) describes the features of the TPS7A63-Q1 and TPS7A6401-Q1 voltage regulators in detail.

7.2 Functional Block Diagrams

Figure 13. TPS7A6333-Q1 and TPS7A6350-Q1 (Fixed Output Voltage With Fault Output)

7.3 Feature Description

7.3.1 Power Up, Reset Delay, and Reset Output

During power up, the regulator incorporates a protection scheme to limit the current through the pass element and output capacitor. When the input voltage exceeds a certain threshold ($V_{IN(POWERUP)}$) level, the output voltage begins to ramp up as shown in Figure 16.

When starting up, and also when the output recovers from a negative voltage spike due to a load step or a dip in the input voltage for a specified duration, the device implements reset delay to indicate that output voltage is stable and in regulation.

When the output voltage reaches the power-on-reset threshold ($V_{TH(POR)}$) level, that is, 93% of regulated output voltage (3.3 V or 5 V, or a programmed value), a constant output current charges an external capacitor (C_{DLY}) to an internal threshold ($V_{TH(RDELAY)}$) voltage level. Then, $nRST$ asserts high and C_{DLY} discharges through an internal load. This allows C_{DLY} to charge from approximately 0 V during the next power cycle.

Program the reset delay time by connecting an external capacitor (C_{DLY} , 100 pF to 100 nF) to the RDELAY pin. Equation 1 gives the delay time:

$$t_{POR} = \frac{C_{DLY} \times 3}{1 \times 10^{-6}}$$

where

- t_{POR} = reset delay time in seconds
- C_{DLY} = reset delay capacitor value in farads

(1)

Figure 16. Power Up and Conditions for Activation of Reset

Figure 17. Reset Delay and Deglitch Filter

As Figure 17 shows, if the regulated output voltage falls below 93% of the set level, $nRST$ asserts low after a short de-glitch time of approximately 5.5 μs (typical). In case of negative transients in the input voltage (V_{IN}), the reset signal asserts low only if the output (V_{OUT}) drops and stays below the reset threshold level ($V_{TH(POR)}$) for more than the deglitch time ($t_{DEGLITCH}$), as Figure 17 and Figure 20 illustrate. While $nRST$ is low, if the input voltage returns to the nominal operating voltage, the normal power-up sequence ensues. $nRST$ asserts high only if the output voltage exceeds the reset threshold voltage ($V_{TH(POR)}$) and the reset delay time (t_{POR}) has elapsed.

Feature Description (continued)

7.3.2 Adjustable Output Voltage

Program the regulated output voltage (V_{OUT}) by connecting external resistors to FB pin. Calculate the feedback resistor values using Equation 2.

$$V_{OUT} = V_{REF} \left[1 + \frac{R1}{R2} \right]$$

where

- V_{OUT} = desired output voltage
- V_{REF} = reference voltage ($V_{REF} = 1.23$ V, typically)
- $R1, R2$ = feedback resistors (see Figure 15)

Equation 3 gives the overall tolerance of the regulated output.

$$\text{tol}_{V_{OUT}} = \text{tol}_{V_{REF}} + \left[\frac{R1}{R1 + R2} \right] [\text{tol}_{R1} + \text{tol}_{R2}]$$

where

- $\text{tol}_{V_{OUT}}$ = tolerance of the output voltage
- $\text{tol}_{V_{REF}}$ = tolerance of the internal reference voltage ($\text{tol}_{V_{REF}} = \pm 1.5\%$ typically)
- $\text{tol}_{R1}, \text{tol}_{R2}$ = tolerance of feedback resistors $R1, R2$

For a tighter tolerance on V_{OUT} , select lower-value feedback resistors. TI recommends to select feedback resistors such that the sum of $R1$ and $R2$ is from 20 k Ω to 200 k Ω .

7.3.3 Chip Enable

These devices have a high-voltage-tolerant EN pin that an external microcontroller or a digital control circuit can use to enable and disable them. A high input to this pin activates the device and turns the regulator on. For self bias applications, connect this input to the VIN terminal. An internal pulldown resistor is connected to this pin, and therefore if this pin remains unconnected, the device stays disabled.

7.3.4 Charge Pump Operation

These devices have an internal charge pump which turns on or off depending on the input voltage and the output current. The charge pump switching circuitry must not cause conducted emissions to exceed required thresholds on the input voltage line. For a given output current, the charge pump stays on at lower input voltages and turns off at higher input voltages. The charge pump switching thresholds are hysteretic. Figure 18 and Figure 19 show typical switching thresholds for the charge pump at light ($I_{OUT} < \text{approximately } 2$ mA) and heavy ($I_{OUT} > \text{approximately } 2$ mA) loads, respectively.

Figure 18. Charge Pump Operation at Light Loads

Figure 19. Charge Pump Operation at Heavy Loads

7.3.5 Low-Power Mode

At light loads and high input voltages ($V_{IN} >$ approximately 8 V, such that the charge pump is off), the device operates in low-power mode and the quiescent current consumption is reduced to 25 μ A (typical) as shown in [Table 1](#).

Table 1. Typical Quiescent Current Consumption

I_{OUT}	Charge Pump ON	Charge Pump OFF
$I_{OUT} <$ approximately 2 mA (Light load)	250 μ A	35 μ A (Low-power mode)
$I_{OUT} >$ approximately 2 mA (Heavy load)	280 μ A	70 μ A

7.3.6 Undervoltage Shutdown

These devices have an integrated undervoltage lockout (UVLO) circuit to shut down the output if the input voltage (V_{IN}) falls below an internally fixed UVLO threshold level ($V_{IN-UVLO}$). This ensures that the regulator does not latch into an unknown state during low input voltage conditions. The regulator powers up when the input voltage exceeds the $V_{IN(POWERUP)}$ level, as [Figure 20](#) shows.

7.3.7 Low-Voltage Tracking

At low input voltages, the regulator drops out of regulation, and the output voltage tracks the input minus a voltage based on the load current (I_{OUT}) and switch resistance (R_{SW}), as [Figure 20](#) shows. This feature allows for a smaller input capacitor and can possibly eliminate the need of using a boost converter during cold crank conditions, as [Figure 20](#) shows.

7.3.8 Integrated Fault Protection

These devices feature integrated fault protection to make them ideal for use in automotive applications. In order to remain in a safe area of operation during certain fault conditions, the devices use internal current-limit protection and current-limit foldback to limit the maximum output current. This protects them from excessive power dissipation. For example, during a short-circuit condition on the output, fault protection limits the current through the pass element to I_{CL} to protect the device from excessive power dissipation.

7.3.9 Thermal Shutdown

These devices incorporate a thermal shutdown (TSD) circuit as a protection from overheating. For continuous normal operation, the junction temperature should not exceed the TSD trip point. The junction temperature exceeding the TSD trip point causes the output to turn off. When the junction temperature falls below TSD trip point, the output turns on again, as [Figure 21](#) shows.

7.3.10 Integrated Window Watchdog

These devices have an integrated watchdog with fault (WD_FLT) and flag (WD_FLAG) output options. Both device options are available in fixed- and adjustable-output versions. The watchdog operation, service fault conditions, and difference between fault (TPS7A63-Q1) and flag (TPS7A6401-Q1) output versions are described as follows.

7.3.10.1 Programmable-Window Watchdog

Program the duration of the watchdog window by connecting an external resistor (R_{OSC}) to ground at the ROSC pin. The current through the resistor sets the clock frequency of the internal oscillator. The user can adjust the duration of the watchdog window (that is, the watchdog timer period) by changing the resistor value. The duration of the watchdog window and the duration of the fault output are multiples of the internal oscillator frequency and are given by the following equations:

$$t_{WD} = 10^{-6} \times R_{OSC} = 5000 \times 1 / f_{OSC} \quad (4)$$

$$t_{WD_OUT} = 1 / f_{OSC} \quad (5)$$

$$t_{CW} = t_{OW} = 1 / 2 t_{WD}$$

where

- t_{WD} = width of watchdog window
- R_{OSC} = resistor connected at ROSC pin
- t_{WD_OUT} = duration of fault output
- f_{OSC} = frequency of internal oscillator
- t_{CW} = duration of closed window
- t_{OW} = duration of open window

(6)

As shown in Figure 22, each watchdog window consists of an open window and a closed window, each having a width approximately 50% of the watchdog window. However, there is an exception to this; the first open window after watchdog initialization is eight times the duration of the watchdog window. All open windows except the one after watchdog initialization are one-half the width of the watchdog window. On initialization, the watchdog must receive service (by software, external microcontroller, and so forth) only during an open window. A watchdog serviced during a closed window, or not serviced during a open window, creates a watchdog fault condition.

Figure 22. Watchdog Window Duration

7.3.10.2 Watchdog Enable

An external microcontroller or a digital circuit can apply an appropriate signal to the nWD_EN pin to enable or disable the watchdog. A low input to this pin turns the watchdog on. Because of an internal pulldown resistor connected to this pin, leaving the pin unconnected keeps the watchdog enabled.

7.3.10.3 Watchdog Service Signal

In order for the watchdog service signal (WD) to service an open window correctly, the service signal must stay high for a duration of at least t_{WD_HOLD} . The recommended value of t_{WD_HOLD} is given by [Equation 7](#):

$$t_{WD_HOLD} = 3 \times t_{WD_OUT} \quad (7)$$

7.3.10.4 Watchdog Fault Outputs

The WD_FLT pin and WD_FLAG pin are fault output terminals for the TPS7A63-Q1 and TPS7A6401-Q1 devices, respectively. Typically, one pulls these fault outputs high to a regulated output supply. In the case of a watchdog fault condition, the TPS7A63-Q1 momentarily pulls WD_FLT low for a duration of t_{WD_OUT} , whereas the TPS7A6401-Q1 latches the WD_FLAG high and momentarily pulls nRST low for a duration of t_{WD_OUT} .

7.3.10.5 Watchdog Initialization

On power up and during normal operation, the watchdog initializes under the conditions shown in [Table 2](#). The normal operation of the watchdog for the WD_FLT and WD_FLAG output device options is shown in [Figure 23](#) and [Figure 24](#), respectively.

Table 2. Conditions For Watchdog Initialization

Edge	What causes watchdog to initialize?	TPS7A63-Q1 (FAULT Option)	TPS7A6401-Q1 (FLAG Option)
	Rising edge of nRST (when V_{OUT} exceeds $V_{TH(POR)}$) while the watchdog is in the enabled state, for example, during soft power up	✓	✓
	Falling edge of nWD_EN while the nRST is already high, for example, when the microprocessor enables the watchdog after the device is powered up	✓	✓
	Rising edge of WD_FLT while the nRST is already high and the watchdog is in the enabled state, for example, right after a closed window is serviced	✓	X

7.3.10.6 Watchdog Operation

Figure 23. Power Up, Initialization, and Normal Operation for TPS7A63-Q1

Figure 24. Power Up, Initialization, and Normal Operation for TPS7A6401-Q1

Figure 23 shows watchdog initialization and operation for the TPS7A63-Q1. After output voltage is in regulation and reset asserts high (clearly the chip-enable pin is high), the watchdog becomes enabled when an external signal pulls nWD_EN (the watchdog enable pin) low. This causes the watchdog to initialize and wait for a service signal during the first open window for $8 \times$ the duration of t_{WD} . A service signal applied to the WD pin during the first open window resets the watchdog counter and a closed window starts. To prevent a fault condition from occurring, watchdog service must not occur during the closed window. Watchdog service must occur during the following open window to prevent fault condition from occurring. The fault output (WD_FLT), externally pulled up to V_{OUT} (typically), stays high as long as the watchdog receives proper serviced and there is no fault condition.

Figure 24 shows watchdog initialization and operation for FLAG output version (TPS7A6401-Q1). The fault output (WD_FLAG), externally pulled up to V_{OUT} (typically), stays low as long as the watchdog receives proper service and there is no fault condition.

Likewise, enabling the watchdog before powering the device on (that is, pulling the nWD_EN pin low before power up), the watchdog initializes as soon as the output voltage is in regulation and reset asserts high (see Table 2 for Conditions for Watchdog Initialization).

7.3.10.7 Watchdog Fault Conditions

Figure 25. Watchdog Service Fault Conditions for TPS7A63-Q1

Figure 26. Watchdog Service Fault Conditions for TPS7A6401-Q1

For both device options, a watchdog fault condition occurs in following (non-exhaustive) cases:

- When the watchdog receives service during a closed window.
- When watchdog does not receive service during an open window (this open window could be the one after watchdog initialization, or the one following a closed window).

As shown in [Figure 25](#), for TPS7A63-Q1 the first watchdog fault registers when the watchdog receives service during a closed window. This causes the watchdog fault pin (WD_FLT) to go low temporarily for a duration of t_{WD_OUT} . Following the fault, the watchdog reinitializes. Likewise, the second fault registers when the watchdog does not receive service during an open window (following a closed window). Again, the fault pin (WD_FLT) is asserts low for a duration of t_{WD_OUT} .

As shown in [Figure 26](#), for TPS7A6401-Q1 the first watchdog fault registers when watchdog receives service during a closes window. This causes the watchdog flag pin (WD_FLAG) to become high and stay latched. At the same time, nRST pin goes low temporarily for the duration of t_{WD_OUT} . WD_FLAG remains high until toggling the nWD_EN pin disables and re-enables the watchdog or the watchdog receives service properly (while nWD_EN is low and nRST is high). The second fault registers when the watchdog does not receive service during an open window (following a closed window). While WD_FLAG is high (that is, during a fault condition), if the watchdog stays enabled, and reset is high; a watchdog service signal can also bring WD_FLAG low (about 5 μ s after the watchdog receives service).

Figure 27. Watchdog Fault During Initialization, and Reinitialization During Reset for TPS7A63-Q1

Figure 28. Watchdog Fault During Initialization, and Reinitialization During Reset for TPS7A6401-Q1

As shown in Figure 27 for the TPS7A6401-Q1, the watchdog fault condition also occurs if the watchdog does not receive service during the open window after watchdog initialization. That is, if the watchdog does not receive service during the first $8 \times t_{WD_OUT}$ period after initialization, a fault condition occurs. This causes the watchdog fault pin (WD_FLT) to go low temporarily for a duration of t_{WD_OUT} . In case of a load transient, if the regulated output voltage drops down causing reset (nRST) to go low, the rising edge on nRST causes the watchdog to reinitialize (that is, when reset becomes high with the watchdog still enabled). During a fault condition (that is, WD_FLT is low) with the watchdog disabled, the fault output continues to stay low until t_{WD_OUT} is elapsed. A falling edge on nWD_EN pin causes the watchdog to reinitialize while nRST is still high.

As shown in Figure 28 for the TPS7A6401-Q1, the watchdog fault condition also occurs if the watchdog does not receive service during the open window after watchdog initialization. That is, if the watchdog does not receive service in first $8 \times t_{WD_OUT}$ period after initialization, a fault condition occurs. This causes the watchdog flag pin (WD_FLAG) to become high and stay latched. At the same time, the nRST pin goes low temporarily for a duration of t_{WD_OUT} . In the case of a load transient, if the regulated output voltage drops down causing the reset output to go low, the WD_FLAG asserts low, and the rising edge on nRST causes the watchdog to reinitialize (while the watchdog remains enabled). During a fault condition (that is, WD_FLAG is high), and with a disabled watchdog, the flag output continues to stay high as long as the watchdog remains enabled or receives proper service. However, nRST stays low until t_{WD_OUT} elapses. Re-enabling the watchdog causes watchdog to reinitialize (while nRST is still high).

7.4 Device Functional Modes

7.4.1 Operation With V_{IN} Lower Than 4 V

The TPS7A63-Q1 and TPS7A6401-Q1 family devices operate with input voltage above 4 V. The typical UVLO voltage is 3.16 V. The device can operate at input voltage lower than 4 V, but at input voltage below the actual UVLO, the device will shut down.

7.4.2 Operation With V_{IN} Larger Than 4 V

When V_{IN} is greater than 4 V, if the input voltage is higher than V_{OUT} plus the dropout voltage, the output voltage is equal to the set value. Otherwise, the output voltage is equal to V_{IN} minus the dropout voltage.

8 Application and Implementation

NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

8.1 Application Information

Typical application circuits for TPS76333-Q1/TPS76350-Q1 and TPS7A6401-Q1 are shown in [Figure 29](#) and [Figure 32](#). Depending on the end application, one may use different values of external components. Carefully select feedback resistors (R1 and R2), used to program the output voltage. Using smaller resistors results in higher current consumption, whereas using very large resistors impacts the sensitivity of the regulator. Therefore, TI recommends selecting feedback resistors such that the sum of R1 and R2 is from 20 k Ω to 200 k Ω .

8.1.1 Example

If the desired regulated output voltage is 5 V, after selecting R2 then one can calculate R1 using (or vice versa) [Equation 2](#). Knowing $V_{REF} = 1.23$ V (typical), $V_{OUT} = 5$ V, selecting R2 = 20 k Ω , the calculated value of R1 is 61.3 k Ω .

During fast load steps, an application may require a larger output capacitor to prevent the output from temporarily dropping down. TI recommends a low-ESR ceramic capacitor with dielectric of type X5R or X7R. One can also connect a bypass capacitor at the output to decouple high-frequency noise as per the end application.

8.2 Typical Applications

8.2.1 Typical Application Using the TPS7A6333-Q1 or TPS7A6350-Q1

Figure 29. Typical Application Schematic, TPS7A6333-Q1/6350-Q1

Typical Applications (continued)

8.2.1.1 Design Requirements

For this design example, use the parameters listed in [Table 3](#).

Table 3. Design Parameters

DESIGN PARAMETER	EXAMPLE VALUES
Input voltage range	7 V - 40 V
Input capacitor range	10 μ F - 22 μ F
Output voltage	3.3 V, 5 V
Output current rating	300 mA maximum
Output capacitor range	1 μ F-10 μ F

8.2.1.2 Detailed Design Procedure

When using the TPS7A6333-Q1, TPS7A6350-Q1, TI recommends adding a 10- μ F to 22- μ F capacitor to the input to keep the input voltage stable. TI also recommends adding a 1- μ F to 10- μ F low ESR ceramic capacitor to get a stable output.

The reset delay time is set by an external capacitor (CDLY) to ground, capacitor value typical from 100 pF to 100 nF. [Equation 1](#) provides the method for the calculation.

Connecting an external resistor to ground at the ROSC pin can set the duration of the watchdog window. [Equation 4](#) provides the method for the calculation. Usually a 10-k Ω to 200-k Ω resistor can be used to set the time.

8.2.1.3 Application Curves

8.2.2 Typical Application Using the TPS7A6401-Q1

Figure 32. Typical Application Schematic TPS7A6401-Q1

8.2.2.1 Design Requirements

For this design example, use the parameters listed in [Table 4](#).

Table 4. Design Parameters

DESIGN PARAMETER	EXAMPLE VALUES
Input voltage range	7 V - 40 V
Input capacitor range	10 µF-22 µF
Output voltage	2.5 V - 7 V
Output current rating	300 mA maximum
Output capacitor range	1 µF-10 µF

8.2.2.2 Detailed Design Procedure

When using TPS7A6401-Q1, TI recommends adding a 10-µF to 22-µF capacitor to the input to keep the input voltage stable. TI also recommends adding a 1-µF to 10-µF low ESR ceramic capacitor to get a stable output.

The output voltage is set by the R1 and R2 resistor network. Output voltage can be calculated by [Equation 2](#).

The reset delay time is set by an external capacitor (CDLY) to ground, capacitor value typical from 100 pF to 100 nF. [Equation 1](#) provides the method for the calculation. Connecting an external resistor to ground at the ROSC pin can set the duration of the watchdog window. [Equation 4](#) provides the method for the calculation. Usually a 10-kΩ to 200-kΩ resistor can be used to set the time.

8.2.2.3 Application Curves

9 Power Supply Recommendations

The device is designed to operate from an input-voltage supply range from 7 V to 40 V. This input supply must be well regulated. If the input supply is located more than a few inches from the TPS7A63XX-Q1 or TPS7A64XX-Q1 device, TI recommends adding an electrolytic capacitor with a value of 10 μ F and a ceramic bypass capacitor at the input.

10 Layout

10.1 Layout Guidelines

For the LDO power supply, especially these high voltage and large current ones, layout is an important step. If layout is not carefully designed, the regulator could not deliver enough output current because of the thermal limitation. To improve the thermal performance of the device, and maximize the current output at high ambient temperature, it is recommended to spread the thermal pad as large as possible and put enough thermal vias on the thermal pad. [Figure 37](#) shows an example layout.

10.1.1 Power Dissipation and Thermal Considerations

Calculated the power dissipated in the device using [Equation 8](#).

$$P_D = I_{OUT} \times (V_{IN} - V_{OUT}) + I_{QUIESCENT} \times V_{IN}$$

where

- P_D = continuous power dissipation
- I_{OUT} = output current
- V_{IN} = input voltage
- V_{OUT} = output voltage
- $I_{QUIESCENT}$ = quiescent current

(8)

As $I_{QUIESCENT} \ll I_{OUT}$, therefore, ignore the term $I_{QUIESCENT} \times V_{IN}$ in [Equation 8](#).

For a device in operation at a given ambient air temperature (T_A), calculate the junction temperature (T_J) using [Equation 9](#).

$$T_J = T_A + (R_{\theta JA} \times P_D)$$

where

- $R_{\theta JA}$ = junction-to-ambient-air thermal impedance

(9)

Calculate the rise in junction temperature due to power dissipation using [Equation 10](#).

Layout Guidelines (continued)

$$\Delta T = T_J - T_A = (R_{\theta JA} \times P_D) \quad (10)$$

For a given maximum junction temperature (T_{J-Max}), calculate the maximum ambient air temperature (T_{A-Max}) at which the device can operate using [Equation 11](#).

$$T_{A-Max} = T_{J-Max} - (R_{\theta JA} \times P_D) \quad (11)$$

10.1.1.1 Example

If $I_{OUT} = 100$ mA, $V_{OUT} = 5$ V, $V_{IN} = 14$ V, $I_{QUIESCENT} = 250$ μ A, and $R_{\theta JA} = 50^\circ\text{C/W}$, the continuous power dissipated in the device is 0.9 W. The rise in junction temperature due to power dissipation is 45°C . For a maximum junction temperature of 150°C , the maximum ambient air temperature at which the device can operate is 105°C .

For adequate heat dissipation, TI recommends soldering the thermal pad (exposed heat sink) to the thermal land pad on the PCB. Doing this provides a heat conduction path from the die to the PCB and reduces overall package thermal resistance. Power derating curves for the TPS7A63-Q1 and TPS7A6401-Q1 PWP package and TPS7A6333-Q1 DRK are comparable; see [Figure 35](#).

Figure 35. Power Derating Curve

For optimum thermal performance, TI recommends using a high-K PCB with thermal vias between the ground plane and solder pad or thermal land pad; see [Figure 36](#) (a) and (b). Further, use a thicker ground plane and a thermal land pad with a larger surface area to improve considerably the heat-spreading capabilities of a PCB. For a two-layer PCB, a bat wing layout can enhance the heat-spreading capabilities.

Layout Guidelines (continued)

(a) Multilayer PCB with a dedicated ground plane

(b) Dual layer PCB with Bat wings for enhanced heat spreading

Figure 36. Using Multilayer PCB and Thermal Vias for Adequate Heat Dissipation

Keeping other factors constant, surface area of the thermal land pad contributes to heat dissipation only to a certain extent.

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

THERMAL INFORMATION

This package incorporates an exposed thermal pad that is designed to be attached directly to an external heatsink. The thermal pad must be soldered directly to the printed circuit board (PCB). After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

- NOTES:
- A. All linear dimensions are in millimeters.
 - B. This drawing is subject to change without notice.
 - C. Body dimensions do not include mold flash or protrusions. Mold flash and protrusion shall not exceed 0.15 per side.
 - D. This package is designed to be soldered to a thermal pad on the board. Refer to Technical Brief, PowerPad Thermally Enhanced Package, Texas Instruments Literature No. SLMA002 for information regarding recommended board layout. This document is available at www.ti.com <<http://www.ti.com>>.
 - E. See the additional figure in the Product Data Sheet for details regarding the exposed thermal pad features and dimensions.
 - E. Falls within JEDEC MO-153

THERMAL INFORMATION

This PowerPAD™ package incorporates an exposed thermal pad that is designed to be attached to a printed circuit board (PCB). The thermal pad must be soldered directly to the PCB. After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For additional information on the PowerPAD package and how to take advantage of its heat dissipating abilities, refer to Technical Brief, PowerPAD Thermally Enhanced Package, Texas Instruments Literature No. SLMA002 and Application Brief, PowerPAD Made Easy, Texas Instruments Literature No. SLMA004. Both documents are available at www.ti.com.

The exposed thermal pad dimensions for this package are shown in the following illustration.

- NOTES:
- All linear dimensions are in millimeters.
 - This drawing is subject to change without notice.
 - Customers should place a note on the circuit board fabrication drawing not to alter the center solder mask defined pad.
 - This package is designed to be soldered to a thermal pad on the board. Refer to Technical Brief, PowerPad Thermally Enhanced Package, Texas Instruments Literature No. SLMA002, SLMA004, and also the Product Data Sheets for specific thermal information, via requirements, and recommended board layout. These documents are available at www.ti.com <<http://www.ti.com>>. Publication IPC-7351 is recommended for alternate designs.
 - Laser cutting apertures with trapezoidal walls and also rounding corners will offer better paste release. Customers should contact their board assembly site for stencil design recommendations. Example stencil design based on a 50% volumetric metal load solder paste. Refer to IPC-7525 for other stencil recommendations.
 - Customers should contact their board fabrication site for solder mask tolerances between and around signal pads.
