Read This First

This document describes the Audio Serial Port (ASP) in the TMS320DM335 Digital Media System-on-Chip (DMSoC). The ASP is a specialized version of the ASP peripheral commonly found in other TI devices.

Notational Conventions

This document uses the following conventions.

- Hexadecimal numbers are shown with the suffix h. For example, the following number is 40 hexadecimal (decimal 64): 40h.
- Registers in this document are shown in figures and described in tables.
 - Each register figure shows a rectangle divided into fields that represent the fields of the register. Each field is labeled with its bit name, its beginning and ending bit numbers above, and its read/write properties below. A legend explains the notation used for the properties.
 - Reserved bits in a register figure designate a bit that is used for future device expansion.

Related Documentation from Texas Instruments

This document describes the Video Processing Back End (VPBE) in the TMS320DM335 Digital Media System-on-Chip (DMSoC).

SPRUFY0 — TMS320DM335 Digital Media System-on-Chip (DMSoC) 64-bit Timer Reference Guide

This document describes the operation of the software-programmable 64-bit timers in the TMS320DM335 Digital Media System-on-Chip (DMSoC). Timer 0, Timer 1, and Timer 3 are used as general-purpose (GP) timers and can be programmed in 64-bit mode, dual 32-bit unchained mode, or dual 32-bit chained mode; Timer 2 is used only as a watchdog timer. The GP timer modes can be used to generate periodic interrupts or enhanced direct memory access (EDMA) synchronization events and Real Time Output (RTO) events (Timer 3 only). The watchdog timer mode is used to provide a recovery mechanism for the device in the event of a fault condition, such as a non-exiting code loop.

SPRUFY1 — TMS320DM335 Digital Media System-on-Chip (DMSoC) Serial Peripheral Interface (SPI)

Reference Guide This document describes the serial peripheral interface (SPI) in the TMS320DM335 Digital Media System-on-Chip (DMSoC). The SPI is a high-speed synchronous serial input/output port that allows a serial bit stream of programmed length (1 to 16 bits) to be shifted into and out of the device at a programmed bit-transfer rate. The SPI is normally used for communication between the DMSoC and external peripherals. Typical applications include an interface to external I/O or peripheral expansion via devices such as shift registers, display drivers, SPI EPROMs and analog-to-digital converters.

[SPRUFZ3](#) — TMS320DM335 Digital Media System-on-Chip (DMSoC) Audio Serial Port (ASP)

Reference Guide This document describes the operation of the audio serial port (ASP) audio interface in the TMS320DM335 Digital Media System-on-Chip (DMSoC). The primary audio modes that are supported by the ASP are the AC97 and IIS modes. In addition to the primary audio modes, the ASP supports general serial port receive and transmit operation, but is not intended to be used as a high-speed interface.

Audio Serial Port (ASP) Interface

1 Introduction

This document describes the operation of the Audio Serial Port (ASP) in the TMS320DM335 Digital Media System-on-Chip (DMSoC). The ASP is a specialized version of the ASP peripheral commonly found in other TI devices.

1.1 Purpose of the Peripheral

The primary use for the audio serial port (ASP) is for audio interface purposes. The primary audio modes that are supported by the ASP are the AC97 and IIS modes. In addition to the primary audio modes, the ASP can be programmed to support other serial formats but is not intended to be used as a high-speed interface.

1.2 Features

The ASP provides the following functions:

- Full-duplex communication
- Double-buffered data registers, which allow a continuous data stream
- Independent framing and clocking for receive and transmit
- Direct interface to industry-standard codecs, analog interface chips (AICs), and other serially connected analog-to-digital (A/D) and digital-to-analog (D/A) devices
- External shift clock or an internal, programmable frequency shift clock for data transfer

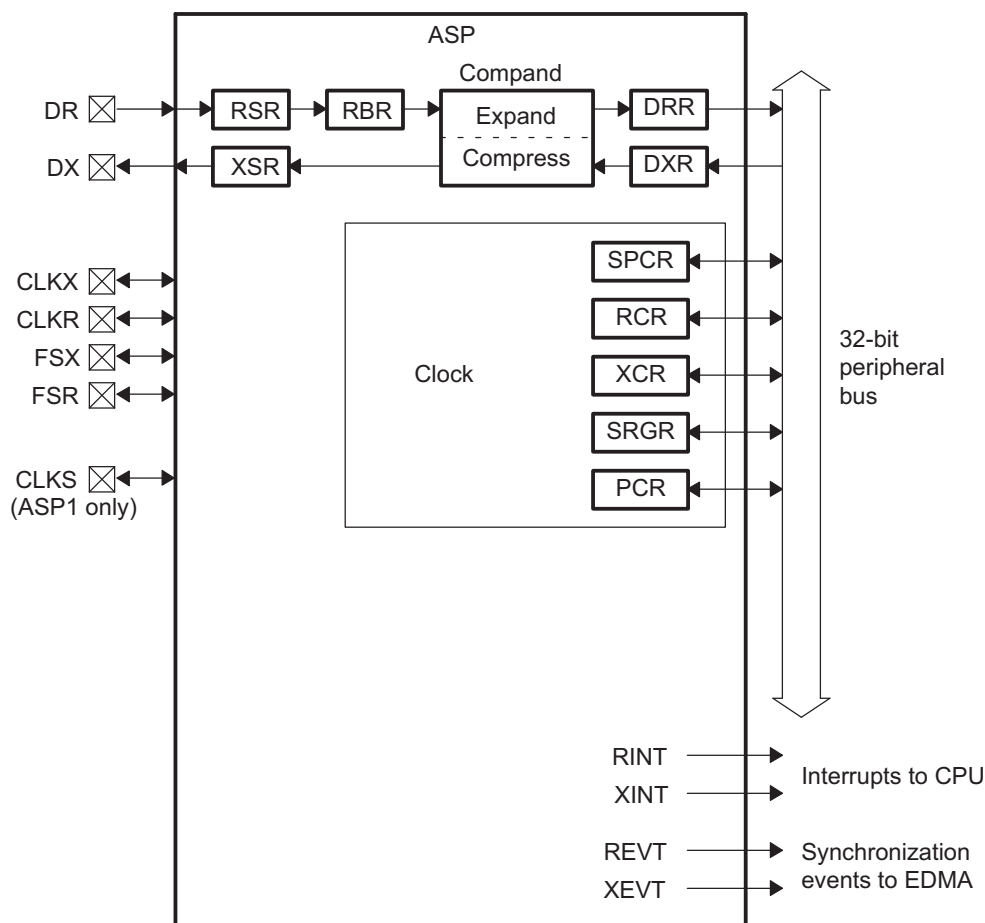

In addition, the ASP has the following capabilities:

- Direct interface to:
 - AC97 compliant devices (the necessary multiphase frame synchronization capability is provided)
 - IIS compliant devices
 - SPI Protocol (master mode only)
- A wide selection of data sizes, including 8, 12, 16, 20, 24, and 32 bits
- -Law and A-Law companding
- 8-bit data transfers with the option of LSB or MSB first
- Programmable polarity for both frame synchronization and data clocks
- Highly programmable internal clock and frame generation

1.3 Functional Block Diagram

The ASP consists of a data path and control path, as shown in [Figure 1](#)

Figure 1. ASP Block Diagram

1.4 Industry Standard Compliance Statement

The ASP supports the following industry standard interfaces:

AC97— The AC97 standard specifies a 5-wire digital serial link between an audio codec device and its digital controller.

IIS— IIS is a protocol for transmitting two channels of digital audio data over a single serial connection. The IIS bus is an industry standard three-wire interface for streaming stereo audio between devices, typically between a CPU and a DAC/ADC.

2 Peripheral Architecture

This section describes the architecture of the ASP.

2.1 Clock Control

The ASP can use an internal or external clock source. The internal clock source to the ASP is an output of the PLL Controller. Either clock source can be divided down inside the ASP to generate the actual interface bit clock frequency. For information on device clocking and the PLL Controller, refer to the *TMS320DM335 Digital Media System-on-Chip (DMSoC) ARM Subsystem Reference Guide (SPRUFX7)*. For detailed timing information, see the device-specific data manual. Detailed information about how the interface clock and frame synchronization signals are generated is provided in [Section 2.3](#).

2.2 Signal Descriptions

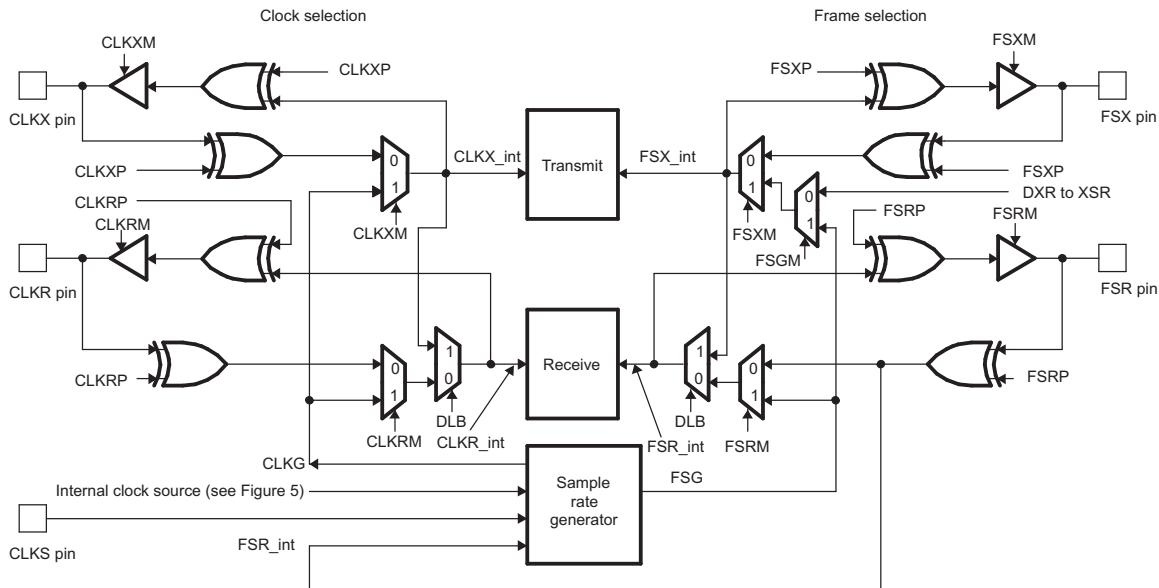

The signals used on the ASP audio interface are listed in [Table 1](#).

Table 1. ASP Interface Signals

Pin	I/O/Z	Description
CLKR	I/O/Z	Receive clock - supplies or receives a reference clock for the receiver; or supplies a reference clock to the sample rate generator
CLKX	I/O/Z	Transmit clock - supplies or receives a reference clock for the transmitter; or supplies a reference clock to the sample rate generator
DR	I	Received serial data
DX	O/Z	Transmitted serial data
FSR	I/O/Z	Receive frame synchronization - control signal to synchronize the start of received data
FSX	I/O/Z	Transmit frame synchronization - control signal to synchronize the start of transmitted data
CLKS	I	External master clock input

2.3 Clock, Frames, and Data

The ASP has several ways of selecting clocking and framing for both the receiver and transmitter. Clocking and framing can be sent to both portions by the sample rate generator. Each portion can select external clocking and/or framing independently. [Figure 2](#) is a block diagram of the clock and frame selection circuitry.

Figure 2. Clock and Frame Generation

2.3.1 Frame and Clock Operation

Receive and transmit frame sync pulses (FSR/X), and clocks (CLKR/X), can either be generated internally by the sample rate generator (see section [Section 2.3.2](#)) or be driven by an external source. The source of frame sync and clock is selected by programming the mode bits, FS(R/X)M and CLK(R/X)M respectively, in the pin control register (PCR).

When FSR and FSX are inputs (FSXM = FSRM = 0), the ASP detects them on the internal falling edge of clock, CLKR_int and CLKX_int, respectively (see [Figure 2](#)). The receive data arriving at the DR pin is also sampled on the falling edge of CLKR_int. These internal clock signals are either derived from external source via the CLK(R/X) pins or driven by the sample rate generator clock (CLKG) internal to the ASP.

When FSR and FSX are outputs driven by the sample rate generator, they are generated (transition to their active state) on the rising edge of the internal clock, CLK(R/X)_int. Similarly, data on DX is output on the rising edge of CLKX_int.

FSRP, FSXP, CLKRP, and CLKXP configure the polarities of FSR, FSX, CLKR, and CLKX. All frame sync signals (FSR_int and FSX_int) internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to the ASP) and FSRP = FSXP = 1, the external active (low) frame sync signals are inverted before being sent to the receiver signal (FSR_int) and transmitter signal (FSX_int). Similarly, if internal synchronization is selected (FSR/FSX are outputs), the internal active (high) sync signals are inverted if the polarity bit FS(R/X)P = 1, before being sent to the FS(R/X) pin. [Figure 2](#) shows this inversion using XOR gates.

On the transmit side, the transmit clock polarity bit, CLKXP, sets the edge used to shift and clock out transmit data. Data is always transmitted on the rising edge of CLKX_int (see [Figure 3](#)). If CLKXP = 1 and external clocking is selected (CLKXM = 0 and CLKX is an input), the external falling-edge-triggered input clock on CLKX is inverted to a rising-edge-triggered clock before being sent to the transmitter. If CLKXP = 1 and internal clocking is selected (CLKXM = 1 and CLKX is an output pin), the internal (rising-edge-triggered) clock, CLKX_int, is inverted before being sent out on the CLKX pin.

Similarly, the receiver can reliably sample data that is clocked (by the transmitter) with a rising-edge clock. The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of CLKR_int (see [Figure 4](#)). Therefore, if CLKRP = 1 and external clocking is selected (CLKRM = 0 and CLKR is an input pin), the external rising-edge triggered input clock on CLKR is inverted to a falling-edge clock before being sent to the receiver. If CLKRP = 1 and internal clocking is selected (CLKRM = 1), the internal falling-edge-triggered clock is inverted to a rising edge before being sent out on the CLKR pin.

In a system where the same clock (internal or external) is used to clock the receiver and transmitter, $CLKRP = CLKXP$. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold times of data around this edge. [Figure 4](#) shows how data clocked by an external serial device using a rising-edge clock can be sampled by the ASP receiver with the falling edge of the same clock.

Figure 3. Transmit Data Clocking

Figure 4. Receive Data Clocking

2.3.2 Sample Rate Generator Clocking and Framing

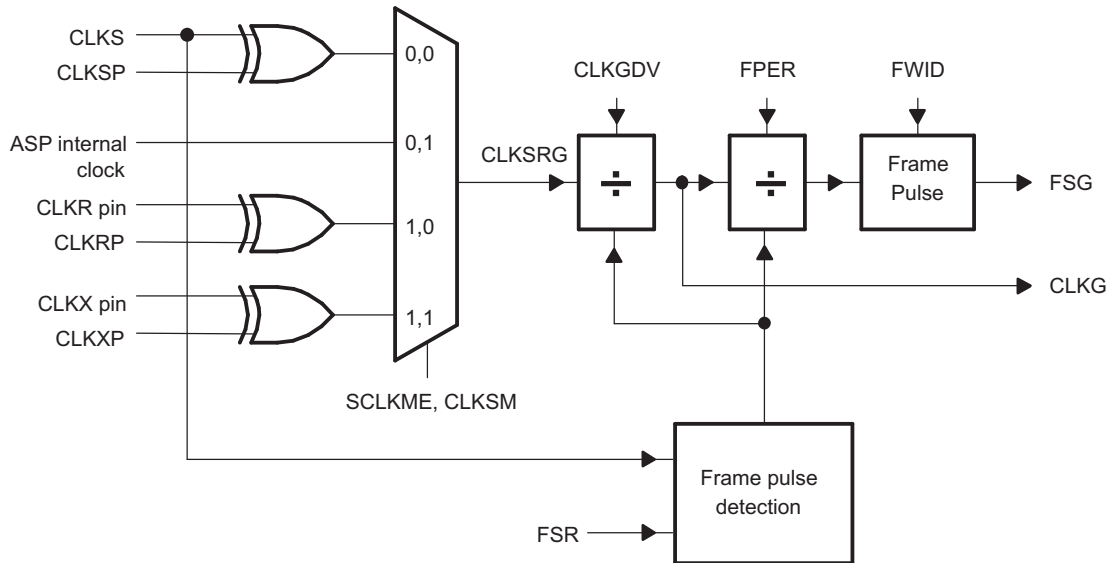

The sample rate generator is composed of a 3-stage clock divider that provides a programmable data clock (CLKG) and framing signal (FSG), as shown in [Figure 5](#). CLKG and FSG are ASP internal signals that can be programmed to drive receive and/or transmit clocking, CLK(R/X), and framing, FS(R/X). The sample rate generator can be programmed to be driven by an internal clock source or an internal clock derived from an external clock source.

The sample rate generator is not used when CLKX, FSX, CLKR, and FSR are driven by an external source. Therefore, the GRST bit in SPCR does not need to be enabled ($GRST = 1$) for this setup. The three stages of the sample rate generator circuit compute:

- Clock divide-down (CLKGDV): The number of input clocks per data bit clock
- Frame period (FPER): The frame period in data bit clocks
- Frame width (FWID): The width of an active frame pulse in data bit clocks

In addition, a frame pulse detection and clock synchronization module allows synchronization of the clock divide-down with an incoming frame pulse. The operation of the sample rate generator during device reset is described in [Section 2.6](#).

Figure 5. Sample Rate Generator Block Diagram

2.3.3 Data Clock Generation

When the receive/transmit clock mode is set to 1 ($CLK(R/X)M = 1$), the data clocks ($CLK(R/X)$) are driven by the internal sample rate generator output clock, $CLKG$. You can select for the receiver and transmitter from a variety of data bit clocks including:

- The input clock to the sample rate generator, which can be either the internal clock source or a dedicated external clock source via the $CLKX$, $CLKR$ or $CLKS$ pins. See Section 2.3.3.1 for details on the source of the ASP internal clock.
- The input clock source (internal clock source or external clock ($CLKX/CLKR/CLKS$)) to the sample rate generator can be divided down by a programmable value ($CLKGDV$) to drive $CLKG$.

Regardless of the source to the sample rate generator, the rising edge of $CLKSRG$ (see Figure 5) generates $CLKG$ and FSG .

2.3.3.1 Input Clock Source Mode: $CLKSM$ and $SCLKME$

The sample rate generator's input clock signal can be driven from one of four sources selectable with the $SCLKME$ bit of the PCR and the $CLKSM$ bit of the SRGR (see Table 2).

Table 2. Choosing an Input Clock for the Sample Rate Generator With the $SCLKME$ and $CLKSM$ Bits

SCLKME	CLKSM	Input Clock For Sample Rate Generator
0	0	Signal on $CLKS$ pin
0	1	ASP internal input clock
1	0	Signal on $CLKR$ pin
1	1	Signal on $CLKX$ pin

2.3.3.2 Sample Rate Generator Data Bit Clock Rate: $CLKGDV$

The first divider stage generates the serial data bit clock from the input clock. This divider stage uses a counter that is preloaded by $CLKGDV$ and that contains the divide ratio value. The output of this stage is the data bit clock that is output on the sample rate generator output, $CLKG$, and that serves as the input for the second and third divider stages.

CLKG has a frequency equal to $1/(\text{CLKGDV} + 1)$ of the sample rate generator input clock. Thus, the sample rate generator input clock frequency is divided by a value between 1 to 256. The CLKGDV value chosen must result in a clock that meets the timing requirements/limitations specified in the device-specific data manual.

When CLKGDV is an odd value or equal to 0, the CLKG duty cycle is 50%. Note that an odd CLKGDV value means an even divide down of the source clock and an even CLKGDV value means an odd divide down of the source clock. When CLKGDV is an even value ($2p$), the high state duration is $p + 1$ cycles and the low state duration is p cycles. This is illustrated in [Example 1](#), [Example 2](#), and [Example 3](#).

In the following examples:

S_{IN} = sample generator input clock period

f_{IN} = sample generator input clock frequency

S_G = CLKG period

f_G = CLKG frequency

The following equation is given above: $f_G = f_{IN}/(\text{CLKGDV} + 1)$; therefore, $S_G = (\text{CLKGDV} + 1) \downarrow S_{IN}$.

Example 1. CLKGDV = 0

$$\text{CLKGDV} = 0$$

$$S_G = (\text{CLKGDV} + 1) \downarrow S_{IN} = (0 + 1) \downarrow S_{IN} = S_{IN}$$

$$\text{Pulse width high} = S_{IN} \downarrow (\text{CLKGDV} + 1)/2 = S_{IN} \downarrow (0 + 1)/2 = 0.5 \downarrow S_{IN}$$

$$\text{Pulse width low} = S_{IN} \downarrow (\text{CLKGDV} + 1)/2 = S_{IN} \downarrow (0 + 1)/2 = 0.5 \downarrow S_{IN}$$

Example 2. CLKGDV = 1

$$\text{CLKGDV} = 1$$

$$S_G = (\text{CLKGDV} + 1) \downarrow S_{IN} = (1 + 1) \downarrow S_{IN} = 2 \downarrow S_{IN}$$

$$\text{Pulse width high} = S_{IN} \downarrow (\text{CLKGDV} + 1)/2 = S_{IN} \downarrow (1 + 1)/2 = S_{IN}$$

$$\text{Pulse width low} = S_{IN} \downarrow (\text{CLKGDV} + 1)/2 = S_{IN} \downarrow (1 + 1)/2 = S_{IN}$$

Example 3. CLKGDV = 2

$$\text{CLKGDV} = 2$$

$$S_G = (\text{CLKGDV} + 1) \downarrow S_{IN} = (2 + 1) \downarrow S_{IN} = 3 \downarrow S_{IN}$$

$$\text{Pulse width high} = S_{IN} \downarrow (\text{CLKGDV}/2 + 1) = S_{IN} \downarrow (2/2 + 1) = 2 \downarrow S_{IN}$$

$$\text{Pulse width low} = S_{IN} \downarrow \text{CLKGDV}/2 = S_{IN} \downarrow 2/2 = 1 \downarrow S_{IN}$$

2.3.3.3 Bit Clock Polarity: CLKSP

The external clock (CLKS) is selected to drive the sample rate generator clock divider by selecting CLKSM = 0 in the sample rate generator register (SRGR) and SCLKME = 0 in the pin control register (PCR). In this case, the CLKSP bit in SRGR selects the edge of CLKS on which sample rate generator data bit clock (CLKG) and frame sync signal (FSG) are generated. Since the rising edge of CLKSRG generates CLKG and FSG, the rising edge of CLKS when CLKSP = 0 or the falling edge of CLKS when CLKSP = 1 causes the transition on CLKG and FSG.

2.3.3.4 Digital Loopback Mode: DLB

DLB mode cannot be used when the ASP is in clock stop mode (CLKSTP = 1x in SPCR). Setting DLB = 1 in SPCR enables digital loopback mode. In DLB mode, DR, FSR, and CLKX are internally connected through multiplexers to DX, FSX, and CLKX, respectively, as shown in Figure 2 and Figure 6. DLB mode allows testing of serial port code without using the external interface of the ASP. CLKX and FSX must be enabled as outputs (CLKXM = FSXM = 1) in DLB mode.

Figure 6. Digital Loopback Mode

2.3.3.5 Receive Clock Selection: DLB, CLKRM

Table 3 shows how the digital loopback bit (DLB) and the CLKRM bit in PCR select the receiver clock. In digital loopback mode (DLB = 1), the transmitter clock drives the receiver. CLKRM determines whether the CLKR pin is an input or an output.

Table 3. Receive Clock Selection

DLB Bit in SPCR	CLKRM Bit in PCR	Source of Receive Clock	CLKR Function
0	0	CLKR acts as an input driven by the external clock and inverted as determined by CLKRP before being used.	Input.
0	1	The sample rate generator clock (CLKG) drives CLKR.	Output. CLKG inverted as determined by CLKRP before being driven out on CLKR.
1	0	CLKX_int drives the receive clock CLKR_int as selected and is inverted.	High impedance.
1	1	CLKX_int drives CLKR_int as selected and is inverted.	Output. CLKR (same as CLKX) is inverted as determined by CLKRP before being driven out.

2.3.3.6 Transmit Clock Selection: CLKXM

Table 4 shows how the CLKXM bit in PCR selects the transmit clock and whether the CLKX pin is an input or output.

Table 4. Transmit Clock Selection

CLKXM Bit in PCR	Source of Transmit Clock	CLKX Function
0	The external clock drives the CLKX input pin. CLKX is inverted as determined by CLKXP before being used.	Input.
1	The sample rate generator clock (CLKG) drives the transmit clock.	Output. CLKG is inverted as determined by CLKXP before being driven out on CLKX.

2.3.3.7 Stopping Clocks

There are two methods to stop serial clocks between data transfers:

- Using the SPI CLKSTP mode where clocks are stopped between single-element transfers. This is described in [Section 2.8.2](#).
- When the clocks are inputs to the ASP (CLKXM or CLKRM = 0 in the pin control register (PCR)) and the ASP operates in non-SPI mode (the clocks can be stopped between data transfers). If the external device stops the serial clock between data transfers, the ASP interprets it as a slowed-down serial clock. Ensure that there are no glitches on the CLK(R/X) lines as the ASP may interpret them as clock-edge transitions. Restarting the serial clock is equivalent to a normal clock transition after a slow CLK(R/X) cycle. Note that just as in normal operations, transmit under flow (XEMPTY) may occur if the DXR is not properly serviced at least three CLKX cycles before the next frame sync. Therefore, if the serial clock is stopped before DXR is properly serviced, the external device needs to restart the clock at least three CLKX cycles before the next frame sync to allow the DXR write to be properly synchronized. See [Figure 26](#) for a graphical explanation on when DXR needs to be written to avoid underflow.

2.3.4 Frame Sync Generation

Data frame synchronization is independently programmable for the receiver and the transmitter for all data delay values. When the FRST bit in the serial port control register (SPCR) is set to 1 the frame generation logic is activated to generate frame sync signals, provided that FSGM = 1 in the sample rate generator register (SRGR). The frame sync programming options are:

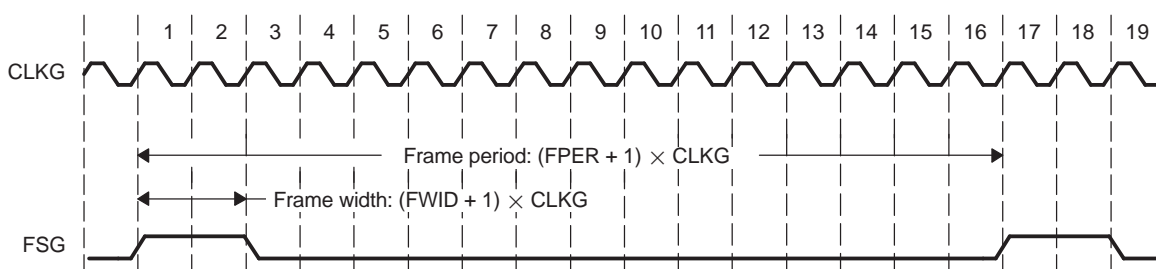

- A frame pulse with a programmable period between sync pulses and a programmable active width specified in SRGR.
- The transmitter can trigger its own frame sync signal that is generated by a DXR-to-XSR copy. This causes a frame sync to occur on every DXR-to-XSR copy. The data delays can be programmed as required. However, maximum packet frequency cannot be achieved in this method for data delays of 1 and 2.
- Both the receiver and transmitter can independently select an external frame synchronization on the FSR and FSX pins, respectively.

2.3.4.1 Frame Period (FPER) and Frame Width (FWID)

The FPER bits in the sample rate generator register (SRGR) are a 12-bit down-counter that can count down the generated data clocks from 4095 to 0. FPER controls the period of active frame sync pulses. The FWID bits are an 8-bit down-counter. FWID controls the active width of the frame sync pulse.

When the sample rate generator comes out of reset, FSG is in an inactive (low) state. After this, when FRST = 1 and FSGM = 1, frame sync signals are generated. The frame width value (FWID + 1) is counted down on every CLKG cycle until it reaches 0 when FSG goes low. Thus, the value of FWID + 1 determines an active frame pulse width ranging from 1 to 256 data bit clocks. At the same time, the frame period value (FPER + 1) is also counting down, and when this value reaches 0, FSG goes high again, indicating a new frame is beginning. Thus, the value of FPER + 1 determines a frame length from 1 to 4096 data bits. [Figure 7](#) shows a frame of 16 CLKG periods (FPER = 15 or 0000 1111b). It is recommended that FWID be programmed to a value less than (R/X)WDLEN1/2."

Figure 7. Programmable Frame Period and Width

2.3.4.2 Receive Frame Synchronization Selection: DLB and FSRM

Table 5 shows how you can select various sources to provide the receive frame synchronization signal. Note that in digital loopback mode (DLB = 1), the transmit frame sync signal is used as the receive frame sync signal and that DR is internally connected to DX.

Note: FSR_int and FSX_int are shown in Figure 2.

Table 5. Receive Frame Synchronization Selection

DLB Bit in SPCR	FSRM Bit in PCR	Source of Receive Frame Synchronization	FSR Pin Function
0	0	External frame sync signal drives the FSR input pin, whose signal is then inverted as determined by FSRP before being used as FSR_int.	Input.
0	1	Sample rate generator frame sync signal (FSG) drives FSR_int, FRST = 1.	Output. FSG is inverted as determined by FSRP before being driven out on the FSR pin.
1	0	FSX_int drives FSR_int. FSX is selected as shown in Table 6.	High impedance.
1	1	FSX_int drives FSR_int and is selected as shown in Table 6.	Output. Receive (same as transmit) frame synchronization is inverted as determined by FSRP before being driven out.

2.3.4.3 Transmit Frame Synchronization Selection: FSXM and FSGM

Table 6 shows how you can select the source of the transmit frame synchronization signal. The three choices are:

- External frame sync input
- The sample rate generator frame sync signal, FSG
- A signal that indicates a DXR-to-XSR copy has been made

Note: FSR_int and FSX_int are shown in Figure 2.

Table 6. Transmit Frame Synchronization Selection

FSXM Bit in PCR	FSGM Bit in SRGR	Source of Transmit Frame Synchronization	FSX Pin Function
0	X	External frame sync input on the FSX pin. This is inverted by FSXP before being used as FSX_int.	Input.
1	1	Sample rate generator frame sync signal (FSG) drives FSX_int. FRST = 1.	Output. FSG is inverted by FSXP before being driven out on FSX.
1	0	A DXR-to-XSR copy activates transmit frame sync signal.	Output. 1-bit-clock-wide signal inverted as determined by FSXP before being driven out on FSX.

2.3.4.4 Frame Detection

To facilitate detection of frame synchronization, the receive and transmit CPU interrupts (RINT and XINT) can be programmed to detect frame synchronization by setting $RINTM = XINTM = 10b$ in the serial port control register (SPCR). The associated portion (receiver/transmitter) of the ASP *must be out of reset*.

2.3.5 Data and Frames

2.3.5.1 Frame Synchronization Phases

Frame synchronization indicates the beginning of a transfer on the ASP. The data stream following frame synchronization can have up to two phases, phase 1 and phase 2. The number of phases can be selected by the phase bit, (R/X)PHASE, in RCR and XCR. The number of elements per frame and bits per element can be independently selected for each phase via (R/X)FRLEN1/2 and (R/X)WDLEN1/2, respectively. [Figure 8](#) shows a frame in which the first phase consists of two elements of 12 bits, each followed by a second phase of three elements of 8 bits each. The entire bit stream in the frame is contiguous; no gaps exist either between elements or phases. [Table 7](#) shows the fields in the receive/transmit control registers (RCR/XCR) that control the frame length and element length for each phase for both the receiver and the transmitter. The maximum number of elements per frame is 128 for a single-phase frame and 256 elements in a dual-phase frame. The number of bits per element can be 8, 12, 16, 20, 24, or 32.

Note: For a dual-phase frame with internally generated frame synchronization, the maximum number of elements per phase depends on the word length. This is because the frame period, FPER, is only 12-bits wide and, therefore, provides 4096 bits per frame. Hence, the maximum number of 256 elements per dual-phase frame applies only when the WDLEN is 16 bits. However, any combination of element numbers and element size (defined by the FRLEN and WDLEN bits, respectively) is valid as long as their product is less than or equal to 4096 bits. This limitation does not apply for dual-phase with external frame sync.

Table 7. RCR/XCR Fields Controlling Elements per Frame and Bits per Element

Serial Port	Frame Phase	RCR/XCR Field Control	
		Elements per Frame	Bits per Element
Receive	1	RFRLEN1	RWDLEN1
Receive	2	RFRLEN2	RWDLEN2
Transmit	1	XFRLEN1	XWDLEN1
Transmit	2	XFRLEN2	XWDLEN2

2.3.5.2 Frame Length: *RFRLLEN1/2* and *XRRLLEN1/2*

Frame length specifies the maximum number of serial elements or logical time slots or channels that are available for transfer per frame synchronization signal. The 7-bit (R/X)FRLLEN1/2 bits in (R/X)CR support up to 128 elements per phase in a frame, as shown in [Table 8](#). (R/X)PHASE = 0 selects a single-phase data frame, and (R/X)PHASE = 1 selects a dual-phase frame for the data stream. For a single-phase frame, the value of (R/X)FRLLEN2 does not matter. Program the frame length fields with (*w* minus 1), where *w* represents the number of elements per frame. For [Figure 8](#), (R/X)FRLLEN1 = 1 or 000 0001b and (R/X)FRLLEN2 = 2 or 000 0010b.

Table 8. Receive/Transmit Frame Length Configuration

(R/X)PHASE	(R/X)FRLLEN1	(R/X)FRLLEN2	Frame Length
0	$0 \leq n \leq 127$	x	Single-phase frame; (n+1) elements per frame
1	$0 \leq n \leq 127$	$0 \leq m \leq 127$	Dual-phase frame; (n+1) plus (m+1) elements per frame

2.3.5.3 Element Length: *RWDLEN1/2* and *XWDLEN1/2*

The (R/X)WDLEN1/2 fields in the receive/transmit control register (RCR and XCR) determine the element length in bits per element for the receiver and the transmitter for each phase of the frame, as indicated in [Table 7](#). [Table 9](#) shows how the value of these fields selects particular element lengths in bits. For the example in [Figure 8](#), (R/X)WDLEN1 = 001b and (R/X)WDLEN2 = 000b. If (R/X)PHASE = 0, indicating a single-phase frame, (R/X)WDLEN2 is not used by the ASP and its value does not matter.

Table 9. Receive/Transmit Element Length Configuration

(R/X)WDLEN1/2	Element Length (Bits)
000	8
001	12
010	16
011	20
100	24
101	32
110	Reserved
111	Reserved

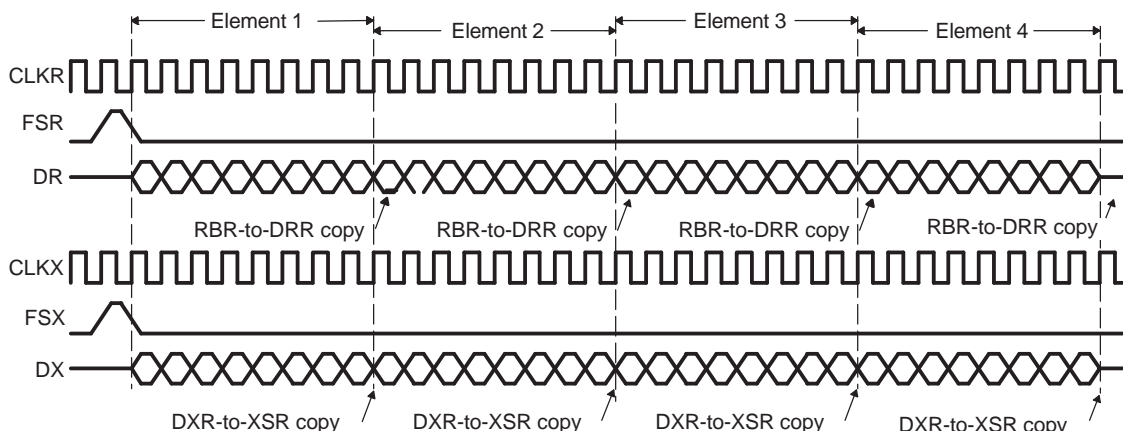

2.3.5.4 Data Packing Using Frame Length and Element Length

The frame length and element length can be manipulated to effectively pack data. For example, consider a situation in which four 8-bit elements are transferred in a single-phase frame, as shown in [Figure 9](#). In this case:

- (R/X)PHASE = 0, indicating a single-phase frame
- (R/X)FRLLEN1 = 000 0011b, indicating a 4-element frame
- (R/X)WDLEN1 = 000b, indicating 8-bit elements

In this example, four 8-bit data elements are transferred to and from the ASP by the CPU or the EDMA controller. Four reads of DRR and four writes of DXR are necessary for each frame.

Figure 9. Single-Phase Frame of Four 8-Bit Elements

The example in [Figure 9](#) can also be viewed as a data stream of a single-phase frame of one 32-bit data element, as shown in [Figure 10](#). In this case:

- (R/X)PHASE = 0, indicating a single phase frame
- (R/X)FRLLEN1 = 0, indicating a 1-element frame
- (R/X)WDLEN1 = 101b, indicating 32-bit elements

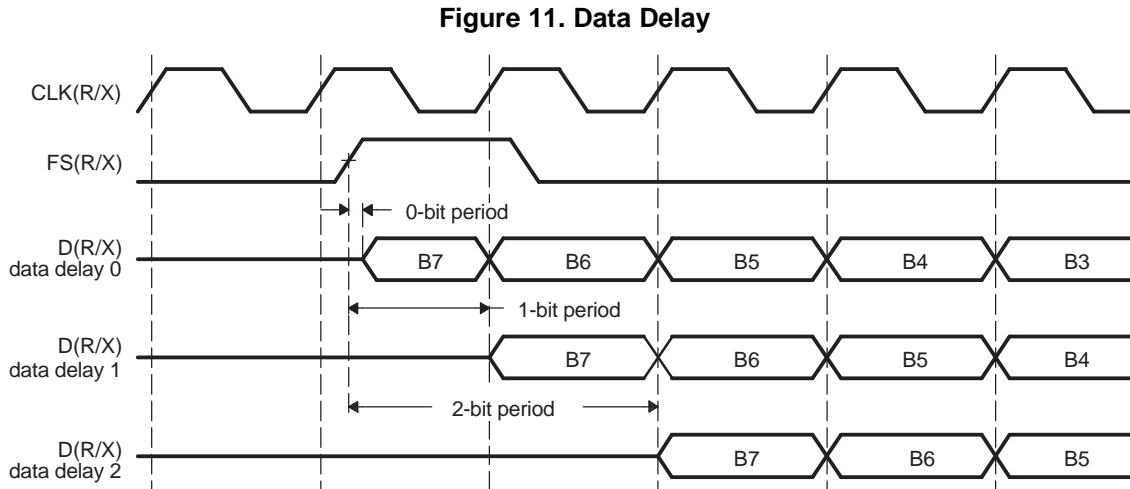

In this example, one 32-bit data element is transferred to and from the ASP by the CPU or the EDMA controller. Thus, one read of DRR and one write of DXR is necessary for each frame. As a result, the number of transfers is one-fourth that of the previous example ([Figure 9](#)). This manipulation reduces the percentage of bus time required for serial port data movement.

Figure 10. Single-Phase Frame of One 32-Bit Element

2.3.5.5 Data Delay: RDATDLY and XDATDLY

The start of a frame is defined by the first clock cycle in which frame synchronization is active. The beginning of actual data reception or transmission with respect to the start of the frame can be delayed if required. This delay is called data delay. RDATDLY (in RCR) and XDATDLY (in XCR) specify the data delay for reception and transmission, respectively. The range of programmable data delay is zero to two bit clocks ((R/X)DATDLY = 00b to 10b), as shown in Figure 11. Typically, a 1-bit delay is selected because data often follows a 1-cycle active frame sync pulse.

Normally a frame sync pulse is detected or sampled with respect to an edge of serial clock CLK(R/X). Thus, on a subsequent cycle (depending on data delay value), data can be received or transmitted. However, in the case of a 0-bit data delay, the data must be ready for reception and/or transmission on the same serial clock cycle. For reception, this problem is solved by receive data being sampled on the first falling edge of CLKX when an active (high) FSR is detected. However, data transmission must begin on the rising edge of CLKX that generated the frame synchronization. Therefore, the first data bit is assumed to be in the XSR and DX. The transmitter then asynchronously detects the frame synchronization, FSX goes active, and it immediately starts driving the first bit to be transmitted on the DX pin.

2.3.5.6 Receive Data Justification and Sign Extension: RJUST

RJUST in SPCR selects whether data in RBR is right- or left-justified (with respect to the MSB) in the DRR. If right justification is selected, RJUST further selects whether the data is sign-extended or zero-filled. Table 10 summarizes the effect that various values of RJUST have on an example 12-bit receive data value ABCh.

Table 10. Effect of RJUST Bit Values With 12-Bit Example Data ABCh

RJUST Bits Value	Justification	Extension	Value in DRR
00	Right	Zero-fill MSBs	0000 0ABCh
01	Right	Sign-extend MSBs	FFFF FABCh
10	Left	Zero-fill LSBs	ABC0 0000h
11	Reserved	Reserved	Reserved

Table 11. Effect of RJUST Bit Values With 20-Bit Example Data ABCDEh

RJUST Bit in SPCR	Justification	Extension	Value in DRR
00	Right	Zero-fill MSBs	000A BCDEh
01	Right	Sign-extend MSBs	FFFA BCDEh
10	Left	Zero-fill LSBs	ABCD E000h
11	Reserved	Reserved	Reserved

2.3.5.7 32-Bit Bit Reversal: RWDREVRS, XWDREVRS

Normally all transfers are sent and received with the MSB first; however, you can reverse the receive/transmit bit ordering of a 32-bit element (LSB first) using the 32-bit reversal feature of the ASP by setting all of the following:

- (R/X)WDREVRS = 1 in the receive/transmit control register (RCR/XCR).
- (R/X)COMPAND = 01b in RCR/XCR.
- (R/X)WDLEN(1/2) = 101b in RCR/XCR to indicate 32-bit elements.

When you set the register fields as above, the bit ordering of the 32-bit element is reversed before being received by or sent from the serial port. If the (R/W)WDREVRS and (R/X)COMPAND fields are set as above, but the element size is not set to 32-bit, operation is undefined.

2.4 ASP Standard Operation

During a serial transfer, there are typically periods of serial port inactivity between packets or transfers. The receive and transmit frame synchronization pulse occurs for every serial transfer. When the ASP is not in the reset state and has been configured for the desired operation, a serial transfer can be initiated by programming (R/X)PHASE = 0 for a single-phase frame with the required number of elements programmed in (R/X)FRLLEN1. The number of elements can range from 1 to 128 ((R/X)FRLLEN1 = 00h to 7Fh). The required serial element length is set in the (R/X)WDLEN1 field in the (R/X)CR. If a dual-phase frame is required for the transfer, RPHASE = 1 and each (R/X)FRLLEN1/2 can be set to any value between 0h and 7Fh.

Figure 12 shows a single-phase data frame of one 8-bit element. Since the transfer is configured for a 1-bit data delay, the data on the DX and DR pins are available one bit clock after FS(R/X) goes active. This figure, as well as all others in this section, use the following assumptions:

- (R/X)PHASE = 0, specifying a single-phase frame
- (R/X)FRLLEN1 = 0b, specifying one element per frame
- (R/X)WDLEN1 = 000b, specifying eight bits per element
- (R/X)FRLLEN2 = (R/X)WDLEN2 = Value is ignored
- CLK(R/X)P = 0, specifying that the receive data is clocked on the falling edge and that transmit data is clocked on the rising edge
- FS(R/X)P = 0, specifying that active (high) frame sync signals are used
- (R/X)DATDLY = 01b, specifying a 1-bit data delay

Figure 12. ASP Standard Operation

2.4.1 Receive Operation

Figure 13 shows serial reception. Once the receive frame synchronization signal (FSR) transitions to its active state, it is detected on the first falling edge of the receivers CLKR. The data on the DR pin is then shifted into the receive shift register (RSR) after the appropriate data delay as set by RDATDLY. The contents of RSR is copied to RBR at the end of every element on the rising edge of the clock, provided RBR is not full with the previous data. Then, an RBR-to-DRR copy activates the RRDY status bit to 1 on the following falling edge of CLKR. This indicates that the receive data register (DRR) is ready with the data to be read by the CPU or the EDMA controller. RRDY is deactivated when the DRR is read by the CPU or the EDMA controller. See also Section 2.9.1.2 and Section 2.10.1.

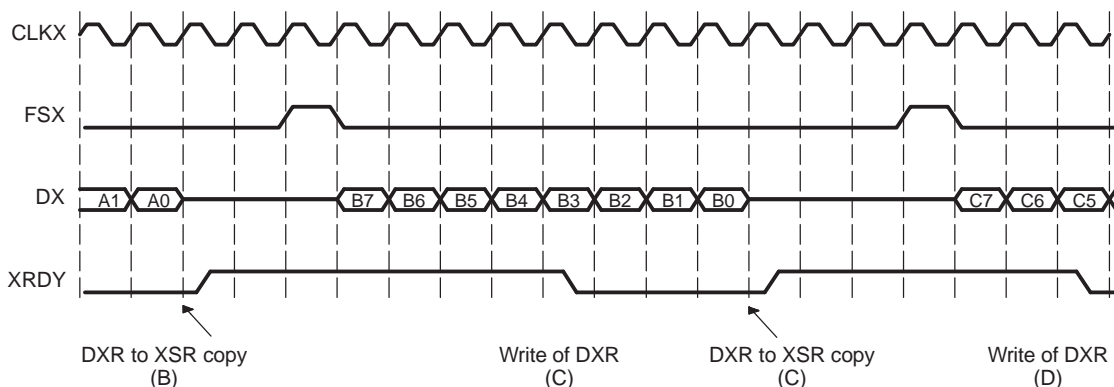

Figure 13. Receive Operation

2.4.2 Transmit Operation

Once transmit frame synchronization occurs, the value in the transmit shift register (XSR) is shifted out and driven on the DX pin after the appropriate data delay as set by XDATDLY. XRDY is activated after every DXR-to-XSR copy on the following falling edge of CLKX, indicating that the data transmit register (DXR) can be written with the next data to be transmitted. XRDY is deactivated when the DXR is written by the CPU or the EDMA controller. Figure 14 illustrates serial transmission. See Section 2.4.5.4 for information on transmit operation when the transmitter is pulled out of reset (XRST = 1). See also Section 2.9.1.3 and Section 2.10.2.

Figure 14. Transmit Operation

2.4.3 Maximum Frame Frequency

The frame frequency is determined by the following equation, which calculates the period between frame synchronization signals:

$$\text{Frame frequency} = \frac{\text{Bit-clock frequency}}{\text{Number of bit clocks between frame sync signals}}$$

The frame frequency may be increased by decreasing the time between frame synchronization signals in bit clocks (which is limited only by the number of bits per frame). As the frame transmit frequency is increased, the inactivity period between the data frames for adjacent transfers decreases to 0. The minimum time between frame synchronization pulses is the number of bits transferred per frame. This time also defines the maximum frame frequency, which is calculated by the following equation:

$$\text{Maximum frame frequency} = \frac{\text{Bit-clock frequency}}{\text{Number of bits per frame}}$$

Figure 15 shows the ASP operating at maximum frame frequency. The data bits in consecutive frames are transmitted continuously with no inactivity between bits. If there is a 1-bit data delay, as shown, the frame synchronization pulse overlaps the last bit transmitted in the previous frame.

Figure 15. Maximum Frame Frequency for Transmit and Receive

Note: For (R/X)DATDLY = 0, the first bit of data transmitted is asynchronous to CLKX, as shown in Figure 11.

Note: Maximum frame frequency may not be possible when the word length is 8-bits, depending on the the clock divide value CLKGDV. The CPU or EDMA may not be able to service serial port requests that occur as frequently as every 8 bit clocks. This situation can be resolved by allowing additional space between words or choosing a slower bit clock (larger CLKGDV value).

2.4.4 Frame Synchronization Ignore

The ASP can be configured to ignore transmit and receive frame synchronization pulses. The (R/X)FIG bit in (R/X)CR can be cleared to 0 to recognize frame sync pulses, or it can be set to 1 to ignore frame sync pulses. In this way, you can use (R/X)FIG either to pack data, if operating at maximum frame frequency, or to ignore unexpected frame sync pulses.

2.4.4.1 Frame Sync Ignore and Unexpected Frame Sync Pulses

RFIG and XFIG are used to ignore unexpected internal or external frame sync pulses. Any frame sync pulse is considered unexpected if it occurs one or more bit clocks earlier than the programmed data delay from the end of the previous frame specified by ((R/X)DATDLY). Setting the frame ignore bits to 1 causes the serial port to ignore these unexpected frame sync signals.

In reception, if not ignored (RFIG = 0), an unexpected FSR pulse discards the contents of RSR in favor of the incoming data. Therefore, if RFIG = 0, an unexpected frame synchronization pulse aborts the current data transfer, sets RSYNCERR in SPCR to 1, and begins the reception of a new data element. When RFIG = 1, the unexpected frame sync pulses are ignored.

In transmission, if not ignored (XFIG = 0), an unexpected FSX pulse aborts the ongoing transmission, sets the XSYNCERR bit in SPCR to 1, and reinitiates transmission of the current element that was aborted. When XFIG = 1, unexpected frame sync signals are ignored.

Figure 16 shows that element B is interrupted by an unexpected frame sync pulse when (R/X)FIG = 0. The reception of B is aborted (B is lost), and a new data element (C) is received after the appropriate data delay. This condition causes a receive synchronization error and thus sets the RSYNCERR bit. However, for transmission, the transmission of B is aborted and the same data (B) is retransmitted after the appropriate data delay. This condition is a transmit synchronization error and thus sets the XSYNCERR bit. Synchronization errors are discussed in Section 2.4.5.2 and Section 2.4.5.5.

Figure 16. Unexpected Frame Synchronization With (R/X)FIG = 0

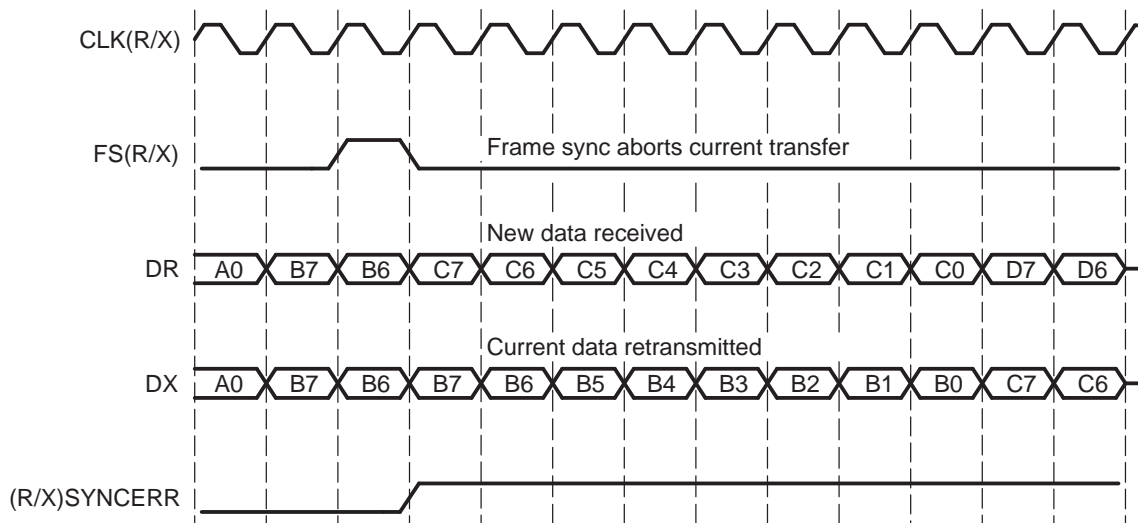

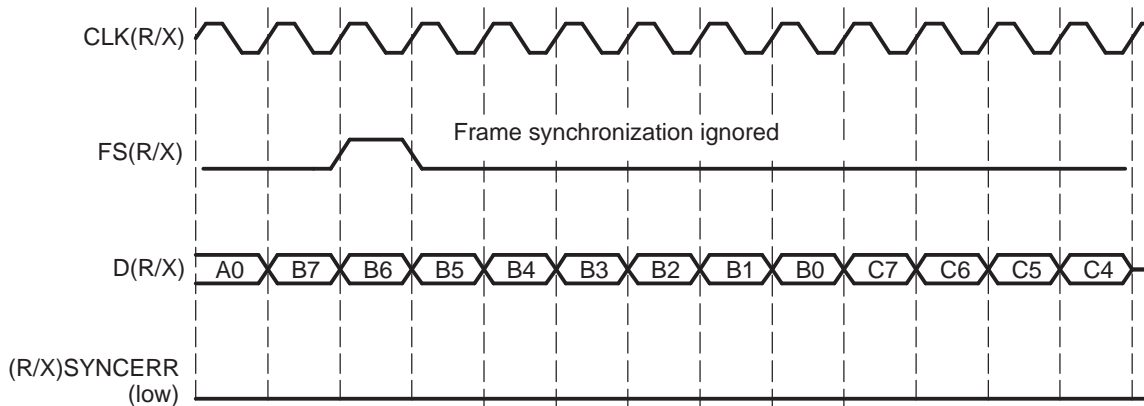

Figure 17 shows ASP operation when unexpected internal or external frame synchronization signals are ignored by setting (R/X)FIG = 1. Here, the transfer of element B is not affected by an unexpected frame synchronization.

Figure 17. Unexpected Frame Synchronization With (R/X)FIG = 1

2.4.4.2 Data Packing using Frame Sync Ignore Bits

Section 2.3.5.4 describes one method of changing the element length and frame length to simulate 32-bit serial element transfers, thus requiring much less bus bandwidth than four 8-bit transfers require. This example works when there are multiple elements per frame.

Now consider the case of the ASP operating at maximum packet frequency, as shown in Figure 18. Here, each frame has only a single 8-bit element. This stream takes one read transfer and one write transfer for each 8-bit element. Figure 19 shows the ASP configured to treat this stream as a continuous stream of 32-bit elements. In this example, (R/X)FIG is set to 1 to ignore unexpected subsequent frames. Only one read transfer and one write transfer is needed every 32-bits. This configuration effectively reduces the required bus bandwidth to one-fourth of the bandwidth needed to transfer four 8-bit blocks.

Figure 18. Maximum Frame Frequency Operation With 8-Bit Data

Figure 19. Data Packing at Maximum Frame Frequency With (R/X)FIG = 1

2.4.5 Serial Port Exception Conditions

There are five serial port events that can constitute a system error:

- Receive overrun (RFULL = 1)
- Unexpected receive frame synchronization (RSYNCERR = 1)
- Transmit data overwrite
- Transmit empty (XEMPTY = 0)
- Unexpected transmit frame synchronization (XSYNCERR = 1)

2.4.5.1 Receive Overrun: RFULL

RFULL = 1 in the serial port control register (SPCR) indicates that the receiver has experienced overrun and is in an error condition. RFULL is set when the following conditions are met:

- DRR has not been read since the last RBR-to-DRR transfer.
- RBR is full and an RBR-to-DRR copy has not occurred.
- RSR is full and an RSR-to-RBR transfer has not occurred.

The data arriving on DR is continuously shifted into RSR (Figure 20). Once a complete element is shifted into RSR, an RSR-to-RBR transfer can occur only if an RBR-to-DRR copy is complete. Therefore, if DRR has not been read by the CPU or the EDMA controller since the last RBR-to-DRR transfer (RRDY = 1), an RBR-to-DRR copy does not take place until RRDY = 0. This prevents an RSR-to-RBR copy. New data arriving on the DR pin is shifted into RSR, and the previous contents of RSR are lost. After the receiver starts running from reset, a minimum of three elements must be received before RFULL can be set, because there was no last RBR-to-DRR transfer before the first element.

This data loss can be avoided if DRR is read no later than two and a half CLKR cycles before the end of the third element (data C) in RSR, as shown in Figure 21.

Either of the following events clears the RFULL bit to 0 and allows subsequent transfers to be read properly:

- Reading DRR
- Resetting the receiver (RRST = 0) or the device

Another frame synchronization is required to restart the receiver.

Figure 20 shows the receive overrun condition. Because element A is not read before the reception of element B is complete, B is not transferred to DRR yet. Another element, C, arrives and fills RSR. DRR is finally read, but not earlier than two and one half cycles before the end of element C. New data D overwrites the previous element C in RSR. If RFULL is still set after the DRR is read, the next element can overwrite D if DRR is not read in time.

Figure 21 shows the case in which RFULL is set but the overrun condition is averted by reading the contents of DRR at least two and a half cycles before the next element, C, is completely shifted into RSR. This ensures that a RBR-to-DRR copy of data B occurs before the next element is transferred from RSR to RBR.

Figure 20. Serial Port Receive Overrun

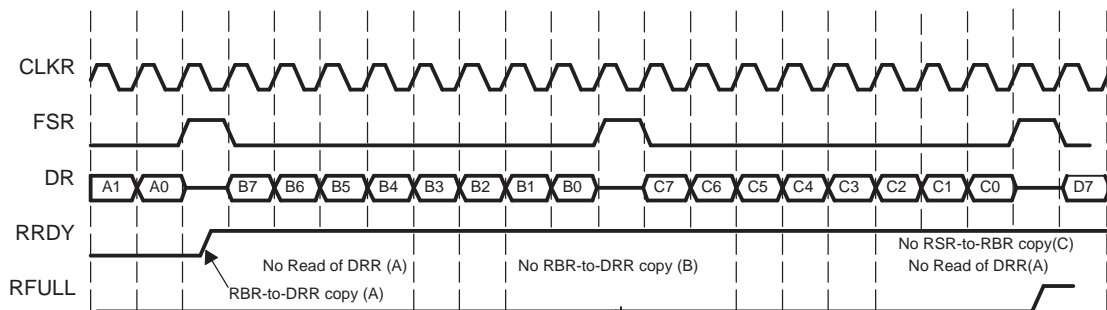

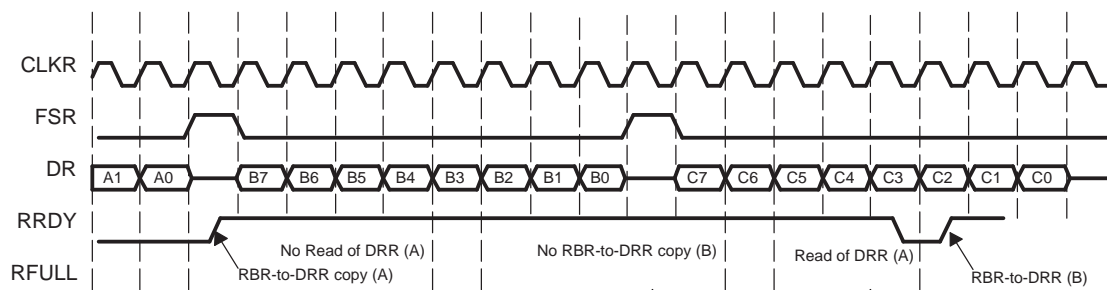

Figure 21. Serial Port Receive Overrun Avoided

2.4.5.2 Unexpected Receive Frame Synchronization: RSYNCERR

Figure 22 shows the decision tree that the receiver uses to handle all incoming frame synchronization pulses. The diagram assumes that the receiver has been activated (RRST = 1). Unexpected frame sync pulses can originate from an external source or from the internal sample rate generator. An unexpected frame sync pulse is defined as a sync pulse which occurs RDATDLY bit clocks earlier than the last transmitted bit of the previous frame. Any one of three cases can occur:

- Case 1: Unexpected FSR pulses with RFIG = 1. This case is discussed in Section 2.4.4.1 and shown in Figure 17. Here, receive frame sync pulses are ignored and the reception continues.
- Case 2: Normal serial port reception. There are three reasons for a receive not to be in progress:
 - This FSR is the first after RRST = 1.
 - This FSR is the first after DRR has been read clearing an RFULL condition.
 - The serial port is in the inter-packet intervals. The programmed data delay (RDATDLY) for reception may start during these inter-packet intervals for the first bit of the next element to be received. Thus, at maximum frame frequency, frame synchronization can still be received RDATDLY bit clocks before the first bit of the associated element.
 For this case, reception continues normally, because these are not unexpected frame sync pulses.
- Case 3: Unexpected receive frame synchronization with RFIG = 0 (unexpected frame not ignored). This case was shown in Figure 16 for maximum packet frequency. Figure 23 shows this case during normal operation of the serial port with time intervals between packets. Unexpected frame sync pulses are detected when they occur the value in RDATDLY bit clocks before the last bit of the previous element is received on DR. In both cases, RSYNCERR in SPCR is set. RSYNCERR can be cleared only by receiver reset or by writing a 0 to this bit in SPCR. If RINTM = 11b in SPCR, RSYNCERR drives the receive interrupt (RINT) to the CPU.

Note: Note that the RSYNCERR bit in SPCR is a read/write bit, so writing a 1 to it sets the error condition. Typically, writing a 0 is expected.

Figure 22. Decision Tree Response to Receive Frame Synchronization Pulse

Figure 23. Unexpected Receive Frame Synchronization Pulse

2.4.5.3 Transmit With Data Overwrite

Figure 24 shows what happens if the data in DXR is overwritten before it is transmitted. Suppose you load the DXR with data C. A subsequent write to the DXR overwrites C with D before C is copied to the XSR. Thus, C is never transmitted on DX. The CPU can avoid overwriting data by polling XRDY before writing to DXR or by waiting for a programmed XINT to be triggered by XRDY (XINTM = 00b). The EDMA controller can avoid overwriting by synchronizing data writes with XEVT. See also Section 2.9.1.3.

Figure 24. Transmit With Data Overwrite

2.4.5.4 Transmit Empty: XEMPTY

XEMPTY indicates whether the transmitter has experienced underflow. Either of the following conditions causes XEMPTY to become active (XEMPTY = 0):

- During transmission, DXR has not been loaded since the last DXR-to-XSR copy, and all bits of the data element in XSR have been shifted out on DX.
- The transmitter is reset (XRST = 0 or the device is reset), and then restarted.

During underflow condition, the transmitter continues to transmit the old data in DXR for every new frame sync signal FSX (generated by an external device, or by the internal sample rate generator) until a new element is loaded into DXR by the CPU or the EDMA controller. XEMPTY is deactivated (XEMPTY = 1) when this new element in DXR is transferred to XSR. In the case when the FSX is generated by a DXR-to-XSR copy (FSXM = 1 in PCR and FSGM = 0 in SRGR), the ASP does not generate any new frame sync until new data is written to the DXR and a DXR-to-XSR copy occurs.

When the transmitter is taken out of reset (XRST = 1), it is in a transmit ready (XRDY = 1) and transmit empty (XEMPTY = 0) condition. If DXR is loaded by the CPU or the EDMA controller before FSX goes active, a valid DXR-to-XSR transfer occurs. This allows for the first element of the first frame to be valid even before the transmit frame sync pulse is generated or detected. Alternatively, if a transmit frame sync is detected before DXR is loaded, 0s are output on DX.

Figure 25 shows a transmit underflow condition. After B is transmitted, B is retransmitted on DX if you fail to reload the DXR before the subsequent frame synchronization. Figure 26 shows the case of writing to DXR just before a transmit underflow condition that would otherwise occur. After B is transmitted, C is written to DXR before the next transmit frame sync pulse occurs.

Figure 25. Transmit Empty

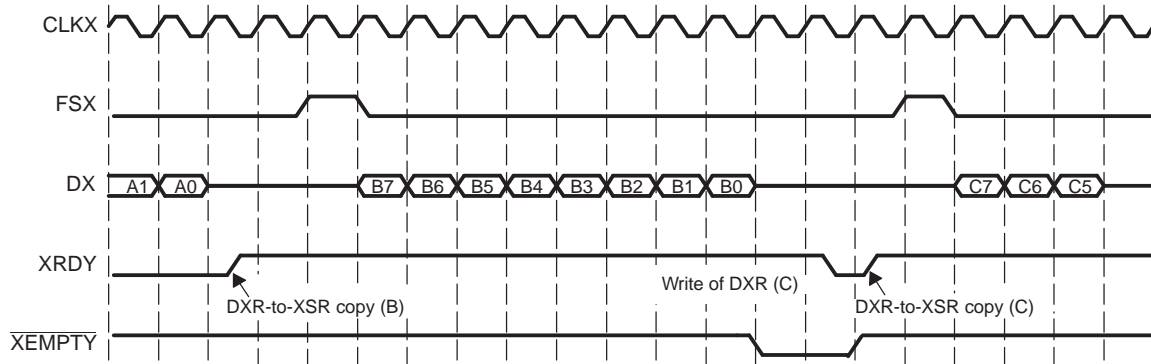

Figure 26. Transmit Empty Avoided

2.4.5.5 Unexpected Transmit Frame Synchronization: XSYNCERR

A transmit frame sync error (XSYNCERR) may occur the first time the transmitter is enabled (XRST = 1) after a device reset. To avoid this, after enabling the transmitter for the first time, the following procedure must be followed:

1. Wait for two CLKG cycles. The unexpected frame sync error (XSYNCERR), if any, occurs within this time period.
2. Disable the transmitter (XRST = 0). This clears any XSYNCERR.
3. Re-enable the transmitter (XRST = 1).

See also [Section 2.7](#) for details on initialization procedure.

[Figure 27](#) shows the decision tree that the transmitter uses to handle all incoming frame synchronization signals. The diagram assumes that the transmitter has been started (XRST = 1). An unexpected transmit frame sync pulse is defined as a sync pulse that occurs XDATDLY bit clocks earlier than the last transmitted bit of the previous frame. Any one of three cases can occur:

- Case 1: Unexpected FSX pulses with XFIG = 1. This case is discussed in [Section 2.4.4.1](#) and shown in [Figure 17](#). In this case, unexpected FSX pulses are ignored, and the transmission continues.
- Case 2: FSX pulses with normal serial port transmission. This situation is discussed in [Section 2.4.2](#). There are two possible reasons for a transmit not to be in progress:
 - This FSX pulse is the first one to occur after XRST = 1.
 - The serial port is in the interpacket intervals. The programmed data delay (XDATDLY) may start during these interpacket intervals before the first bit of the next element is transmitted. Thus, if operating at maximum packet frequency, frame synchronization can still be received XDATDLY bit clocks before the first bit of the associated element.
- Case 3: Unexpected transmit frame synchronization with XFIG = 0. The case was shown in [Figure 16](#) for frame synchronization with XFIG = 0 at maximum packet frequency. [Figure 28](#) shows the case for normal operation of the serial port with interpacket intervals. In both cases, XSYNCERR in SPCR is set. XSYNCERR can be cleared only by transmitter reset or by writing a 0 to this bit in SPCR. If XINTM = 11b in SPCR, XSYNCERR drives the receive interrupt (XINT) to the CPU.

Note: The XSYNCERR bit in SPCR is a read/write bit, so writing a 1 to it sets the error condition. Typically, writing a 0 is expected.

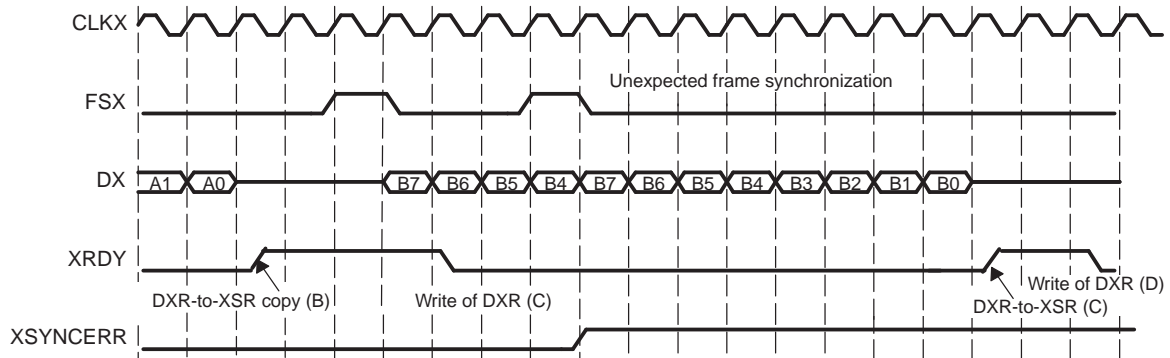

Figure 28. Unexpected Transmit Frame Synchronization Pulse

2.5 -Law/A-Law Companding Hardware Operation

Companding (compressing and expanding) hardware allows compression and expansion of data in either -law or A-law format. The specification for -law and A-law log PCM is part of the CCITT G.711 recommendation. The companding standard employed in the United States and Japan is -law and allows 14 bits of dynamic range. The European companding standard is A-law and allows 13 bits of dynamic range. Any values outside these ranges are set to the most positive or most negative value. Thus, for companding to work best here, the data transferred to and from the ASP via the CPU or the EDMA controller must be at least 16 bits wide.

The -law and A-law formats encode data into 8-bit code elements. Companded data is always 8-bits-wide, so the appropriate (R/X)WDLEN1/2 must be cleared to 0, indicating an 8-bit serial data stream. If companding is enabled and either phase of the frame does not have an 8-bit element length, companding continues as if the element length is eight bits.

When companding is used, transmit data is encoded according to the specified companding law, and receive data is decoded to 2s-complement format. Companding is enabled and the desired format is selected by appropriately setting (R/X)COMPAND in the (R/X)CR. Compression occurs during the process of copying data from DXR to XSR and expansion occurs from RBR to DRR, as shown in [Figure 29](#).

For transmit data to be compressed, it should be 16-bit, left-justified data, such as LAW16, as shown in [Figure 30](#). The value can be either 13 or 14 bits wide, depending on the companding law. This 16-bit data is aligned in DXR, as shown in [Figure 31](#).

For reception, the 8-bit compressed data in RBR is expanded to a left-justified 16-bit data, LAW16. This can be further justified to 32-bit data by programming the RJUST bits in SPCR, as shown in [Table 12](#).

2.5.1 Companding Internal Data

If the ASP is unused, the companding hardware can compand internal data. This hardware can be used to:

- Convert linear data to the appropriate -law or A-law format.
- Convert -law or A-law data to the linear format.
- Observe the quantization effects in companding by transmitting linear data and compressing and re-expanding this data. This is useful only if both XCOMPAND and RCOMPAND enable the same companding format.

Figure 32 shows two methods by which the ASP can compand internal data. Data paths for these two methods are indicated by (DLB) and (non-DLB) arrows.

- **Non-DLB:** When both the transmit and receive sections of the serial port are reset, DRR and DXR are internally connected through the companding logic. Values from DXR are compressed as determined by the XCOMPAND bits and then expanded as determined by the RCOMPAND bits. RRDY and XRDY bits are not set. However, data is available in DRR four internal ASP clocks after being written to DXR. The advantage of this method is its speed. The disadvantage is that there is no synchronization available to the CPU and the EDMA controller to control the flow of data.
- **DLB:** The ASP is enabled in digital loopback (DLB) mode with companding appropriately enabled by the RCOMPAND and XCOMPAND bits. Receive and transmit interrupts (RINT when RINTM = 0 and XINT when XINTM = 0) or synchronization events (REVT and XEVT) allow synchronization of the CPU or the EDMA controller to these conversions, respectively. Here, the time for this companding depends on the serial bit rate selected.

Figure 32. Companding of Internal Data

2.5.2 Bit Ordering

Normally, all transfers on the ASP are sent and received with the MSB first. However, certain 8-bit data protocols (that do not use companded data) require the LSB to be transferred first. By setting the (R/X)COMPAND = 01b in (R/X)CR, the bit ordering of 8-bit elements is reversed (LSB first) before being sent to the serial port. Like the companding feature, this feature is enabled only if the appropriate (R/X)WDLEN1/2 bit is cleared to 0, indicating that 8-bit elements are to be serially transferred.

Note: A 32-bit reversal feature is also available. See [Section 2.3.5.7](#).

2.6 Resetting the Serial Port: RRST, XRST, GRST, and RESET

Device reset or ASP reset: When the ASP is reset by device reset or ASP reset, the state machine is reset to its initial state. All counters and status bits are reset. This includes the receive status bits RFULL, RRDY, and RSYNCERR, and the transmit status bits XEMPTY, XRDY, and XSYNCERR.

The serial port can be reset in the following two ways:

- Device reset (RESET pin is low) places the receiver, the transmitter, and the sample rate generator in reset. When the device reset is removed (RESET = 1), FRST = GRST = RRST = XRST = 0, keeping the entire serial port in the reset state.
- The serial port transmitter and receiver can be independently reset by the XRST and RRST bits in the serial port control register (SPCR). The sample rate generator is reset by the GRST bit in SPCR.

Table 13 shows the state of the ASP pins when the serial port is reset by these methods.

Table 13. Reset State of ASP Pins

Pin	Direction	Device Reset ($\overline{\text{RESET}} = 0$)	ASP Reset
Receiver Reset (RRST = 0 and GRST = 1)			
DR	I	Input	Input
CLKR	I/O/Z	Input	Known state if input; CLKR if output
FSR	I/O/Z	Input	Known state if input; FSRP(inactive state) if output
CLKS	I	Input	Input
Transmitter Reset (XRST = 0 and GRST = 1)			
DX	O/Z	High impedance	High impedance
CLKX	I/O/Z	Input	Known state if input; CLKX if output
FSX	I/O/Z	Input	Known state if input; FSXP(inactive state) if output
CLKS	I	Input	Input

2.6.1 Software Reset Considerations

ASP reset: When the receiver and transmitter reset bits, RRST and XRST, are written with 0, the respective portions of the ASP are reset and activity in the corresponding section stops. All input-only pins, such as DR, and all other pins that are configured as inputs are in a known state. FS(R/X) is driven to its inactive state (same as its polarity bit, FS(R/X)P) if it is an output. If CLK(R/X) are programmed as outputs, they are driven by CLKG, provided that GRST = 1. The DX pin is in the high-impedance state when the transmitter is reset. During normal operation, the sample rate generator can be reset by writing a 0 to GRST. The sample rate generator should only be reset when not being used by the transmitter or the receiver. In this case, the internal sample rate generator clock CLKG, and its frame sync signal (FSG) is driven inactive (low). When the sample rate generator is not in the reset state (GRST = 1), FSR and FSX are in an inactive state when RRST = 0 and XRST = 0, respectively, even if they are outputs driven by FSG. This ensures that when only one portion of the ASP is in reset, the other portion can continue operation when FRST = 1 and frame sync is driven by FSG.

Sample-rate generator reset: As mentioned previously, the sample rate generator is reset when the device is reset or when its reset bit, GRST, is written with 0.

Emulator software reset: In the event of an emulator software reset initiated from the ARM side, the ASP register values are reset to their default values.

2.6.2 Hardware Reset Considerations

Device reset: When the ASP is reset due to device reset, the entire serial port (including the transmitter, receiver, and the sample rate generator) is reset. All input-only pins and 3-state pins should be in a known state. The output-only pin, DX, is in the high-impedance state. When the device is pulled out of reset, the serial port remains in the reset condition (RRST = XRST = FRST = GRST = 0).

2.7 ASP Initialization Procedure

The ASP initialization procedure varies depending on the specific system setup. [Section 2.7.1](#) provides a general initialization sequence.

The transmitter and the receiver of the ASP can operate independently from each other. Therefore, they can be placed in or taken out of reset individually by modifying only the desired bit in the registers without disrupting the other portion. The steps in the following sections discuss the initialization procedure for taking both the transmitter and the receiver out of reset. To initialize only one portion, configure only the portion desired.

The ASP internal sample rate generator and internal frame sync generator are shared between the transmitter and the receiver. [Table 14](#) and [Table 15](#) describe their usage base upon the clock and frame sync configurations of the receiver and transmitter, respectively.

Table 14. Receiver Clock and Frame Configurations

CLKR Source	FSR Source	Comment on Configuration
Internal	Internal	The ASP internal sample rate generator and internal frame sync generator are used by the receiver.
External	Internal	The ASP internal sample rate generator and internal frame sync generator are used by the receiver.
Internal	External	The ASP internal sample rate generator is used but the internal frame sync generator is not used by the receiver.
External	External	The ASP internal sample rate generator and internal frame sync generator are not used by the receiver.

Table 15. Transmitter Clock and Frame Configurations

CLKX Source	FSX Source	Comment on Configuration
Internal	Internal	The ASP internal sample rate generator is used by the transmitter. The transmitter can generate frame sync FSX in one of two ways. First, it can generate FSX by using the internal frame sync generator (FSGM = 1). Alternatively, it can generate FSX upon each DXR-to-XSR copy (FSGM = 0). In this case, the internal frame sync generator can be kept in reset (FRST = 0) if it is not used by the receiver. You can follow the general initialization sequence in Section 2.7.1 .
External	Internal	The ASP internal sample rate generator and internal frame sync generator are not used by the transmitter. This configuration is only valid with FSGM = 0 where the ASP transmitter generates FSX upon each DXR-to-XSR copy. You can follow the general initialization sequence in Section 2.7.1 .
Internal	External	The ASP internal sample rate generator is used by the transmitter but the internal frame sync generator is not.
External	External	The ASP internal sample rate generator and internal frame sync generator are not used by the transmitter.

2.7.1 General Initialization Procedure

This section provides the general initialization procedure.

1. Ensure that no portion of the ASP is using the internal sample rate generator signal CLKG and the internal frame sync generator signal FSG ($GRST = FRST = 0$). The respective portion of the ASP needs to be in reset ($XRST = 0$ and/or $RRST = 0$).
2. Program the control registers as required. Ensure the internal sample rate generator and the internal frame sync generator are still in reset ($GRST = FRST = 0$). Also ensure the respective portion of the ASP is still in reset in this step ($XRST = 0$ and/or $RRST = 0$).
3. Wait for proper internal synchronization. If the external device provides the bit clock, wait for two CLKR or CLKX cycles. If the ASP generates the bit clock as a clock master, wait for two CLKSRG cycles. In this case, the clock source to the sample rate generator (CLKSRG) is selected by the CLKSM bit in SRGR and the SCLKME bit in PCR.
4. Skip this step if the bit clock is provided by the external device. This step only applies if the ASP is the bit clock master and the internal sample rate generator is used.
 - a. Start the sample rate generator by setting the GRST bit to 1. Wait two CLKG bit clocks for synchronization. CLKG is the output of the sample rate generator.
 - b. On the next rising edge of CLKSRG, CLKG transitions to 1 and starts clocking with a frequency equal to $1/(CLKGDV + 1)$ of the sample rate generator source clock CLKSRG.
5. Skip this step if the transmitter is not used. If the transmitter is used, a transmit sync error (XSYNCERR) may occur when it is enabled for the first time after device reset. The purpose of this step is to clear any potential XSYNCERR that occurs on the transmitter at this time:
 - a. Set the XRST bit to 1 to enable the transmitter.
 - b. Wait for any unexpected frame sync error to occur. If the external device provides the bit clock, wait for two CLKR or CLKX cycles. If the ASP generates the bit clock as a clock master, wait for two CLKG cycles. The unexpected frame sync error (XSYNCERR), if any, occurs within this time period.
 - c. Disable the transmitter ($XRST = 0$). This clears any outstanding XSYNCERR.
6. Setup data acquisition as required:
 - a. If the EDMA is used to service the ASP, setup data acquisition as desired and start the EDMA in this step, before the ASP is taken out of reset.
 - b. If CPU interrupt is used to service the ASP, enable the transmit and/or receive interrupt as required.
 - c. If CPU polling is used to service the ASP, no action is required in this step.
7. Set the XRST bit and/or the RRST bit to 1 to enable the corresponding section of the ASP. The ASP is now ready to transmit and/or receive.
 - a. If the EDMA is used to service the ASP, it services the ASP automatically upon receiving the XEVT and/or REVT.
 - b. If CPU interrupt is used to service the ASP, the interrupt service routine is automatically entered upon receiving the XINT and/or RINT.
 - c. If CPU polling is used to service the ASP, it can do so now by polling the XRDY and/or RRDY bit.
8. If the internal frame sync generator is used ($FSGM = 1$), proceed to the additional steps to turn on the internal frame sync generator. Initialization is complete if any one of the following is true:
 - a. The external device generates frame sync FSX and/or FSR. The ASP is now ready to transmit and/or receive upon receiving external frame sync.
 - b. The ASP generates transmit frame sync FSX upon each DXR-to-XSR copy. The internal frame sync generator is not used ($FSGM = 0$).

The following additional steps to turn on the internal frame sync generator apply only if $FSGM = 1$:
9. Skip this step if the transmitter is not used. If the transmitter is used, ensure that DXR is serviced before you start the internal frame sync generator. You can do so by checking $XEMPTY = 1$ (XSR is not empty) in SPCR.
10. Set the FRST bit to 1 to start the internal frame sync generator. The internal frame sync signal FSG is generated on a CLKG active edge after 7 to 8 CLKG clocks have elapsed.

2.7.2 Special Case: External Device is the Transmit Frame Master

Care must be taken if the transmitter expects a frame sync from an external device. After the transmitter comes out of reset ($XRST = 1$), it waits for a frame sync from the external device. If the first frame sync arrives very shortly after the transmitter is enabled, the CPU or EDMA controller may not have a chance to service DXR. In this case, the transmitter shifts out the default data in XSR instead of the desired value, which has not yet arrived in DXR. This causes problems in some applications, as the first data element in the frame is invalid. The data stream appears element-shifted (the first data word may appear in the second channel instead of the first).

To ensure proper operation when the external device is the frame master, you must assure that DXR is already serviced with the first word when a frame sync occurs. To do so, you can keep the transmitter in reset until the first frame sync is detected. Software is setup such that it will only take the transmitter out of reset ($XRST = 1$) promptly after detecting the first frame sync. This assures that the transmitter does not begin data transfers at the data pin during the first frame sync period. This also provides almost an entire frame period for the CPU to service DXR with the first word before the second frame sync occurs. The transmitter only begins data transfers upon receiving the second frame sync. At this point, DXR is already serviced with the first word.

How to Detect First Frame Sync:

Although the ASP is capable of generating an interrupt to the CPU upon the detection of frame synchronization ($SPCR.XINTM = 10b$ and/or $SPCR.RINTM = 10b$), the DM335 ASP requires the associated portion (receiver/transmitter) of the ASP to be out of reset in order for the interrupt to be generated. Therefore instead of directly using the ASP interrupt to detect the first frame sync, on the device you can use the GPIO peripheral. This can be achieved by connecting the frame sync signal to a GPIO pin. Software can either poll the GPIO pin to detect the first frame sync, or program the GPIO peripheral to generate an interrupt to the CPU upon detecting the first frame sync edge. For more information on the GPIO peripheral, see the *TMS320DM335 DMSoC General-Purpose Input/Output (GPIO) User's Guide* ([SPRUFY8](#)).

Here are some recommended GPIO pin(s) on the device that you can use to detect the first ASP external frame sync:

- **GPIO pin located near the ASP pins.** Connect the external frame sync to both the ASP FSX/FSR pin(s) and the dedicated GPIO pin.
- **GPIO pin multiplexed with the ASP FSX signal.** Note that on the device, GPIO pins (of the GPIO peripheral) are multiplexed with the ASP0 pins. Software can program device level pin multiplexing (PINMUX) register to default these pins to GPIO function, and only switch them to ASP function upon detecting the first frame sync.
 - **This method is only recommended if the external device is both the frame sync and clock master**—i.e. the external device drives both the FSX and CLKX signals.
 - **This method is not recommended if the ASP is the clock master** (driving CLKX and/or CLKR), as the “on the fly” pin mux switching can cause a glitch on CLKX/CLKR pin. For more details on pin multiplexing, see device-specific data manual.

Initialization Procedure When External Device is Frame Sync Master

The initialization procedure below assumes the following:

- Using a GPIO pin multiplexed with the ASP FSX signal. If a dedicated GPIO pin is used instead, skip step 1 and step 8b.
- Software polls the GPIO pin to detect first frame sync. If GPIO interrupt is used instead to detect the first frame sync, step 8 can be performed within an interrupt service routine (ISR).
 1. On the device, GPIO and ASP0 signals are multiplexed together. Start by programming the device level pin multiplexing (PINMUX) register to select GPIO function on these GPIO/ASP multiplexed pins. Program the GPIO peripheral so that these pins function as GPIO inputs.
 2. Ensure that no portion of the ASP is using the internal sample rate generator signal CLKG and the internal frame sync generator signal FSG ($GRST = FRST = 0$). The respective portion of the ASP needs to be in reset ($XRST = 0$ and/or $RRST = 0$).
 3. Program the ASP SRGR and other control registers as required. Ensure the internal sample rate generator and the internal frame sync generator are still in reset ($GRST = FRST = 0$). Also ensure the respective portion of the ASP is still in reset in this step ($XRST = 0$ and/or $RRST = 0$).
 4. Wait for proper ASP internal synchronization. If the external device provides the bit clock, wait for

- two CLKR or CLKX cycles. If the ASP generates the bit clock as a clock master, wait for two CLKSRG cycles. In this case, the clock source to the sample rate generator (CLKSRG) is selected by the CLKSM bit in SRGR.
5. Skip this step if the bit clock is provided by the external device. This step only applies if the ASP is the bit clock master and the internal sample rate generator is used.
 - a. Start the sample rate generator by setting the GRST bit to 1. Wait two CLKG bit clocks for synchronization. CLKG is the output of the sample rate generator.
 - b. On the next rising edge of CLKSRG, CLKG transitions to 1 and starts clocking with a frequency equal to $1/(\text{CLKGDV} + 1)$ of the sample rate generator source clock CLKSRG.
 6. A transmit sync error (XSYNCERR) may occur when it is enabled for the first time after device reset. The purpose of this step is to clear any potential XSYNCERR that occurs on the transmitter at this time:
 - a. Set the XRST bit to 1 to enable the transmitter.
 - b. Wait for any unexpected frame sync error to occur. If the external device provides the bit clock, wait for two CLKR or CLKX cycles. If the ASP generates the bit clock as a clock master, wait for two CLKG cycles. The unexpected frame sync error (XSYNCERR), if any, occurs within this time period.
 - c. Disable the transmitter (XRST = 0). This clears any outstanding XSYNCERR.
 7. Setup data acquisition as required:
 - a. If the EDMA controller is used to service the ASP, setup data acquisition as desired and start the EDMA controller in this step, before the ASP is taken out of reset.
 - b. If CPU interrupt is used to service the ASP, no action is required in this step.
 - c. If CPU polling is used to service the ASP, no action is required in this step.
 8. Poll the GPIO pin (through reading the appropriate registers in the GPIO peripheral) to detect the first transmit frame sync from the external device. Upon detection of the first frame sync, perform the following in this order:
 - a. Set the XRST bit and/or the RST bit to 1 to enable the respective portion of the ASP. The ASP is now ready to transmit and/or receive.
 - b. Program the device level PINMUX register to switch the GPIO/ASP multiplexed pins to ASP function.
 9. Service the ASP:
 - a. If CPU polling is used to service the ASP in normal operations, it can do so upon exit from the ISR.
 - b. If CPU interrupt is used to service the ASP in normal operations, upon XRDY interrupt service routine is entered. The ISR should be setup to verify that XRDY = 1 and service the ASP accordingly.
 - c. If EDMA controller is used to service the ASP in normal operations, it services the ASP automatically upon receiving the XEVT and/or REVT.
 10. Upon detection of the second frame sync, DXR is already serviced and the transmitter is ready to transmit the valid data. The receiver is also serviced properly by the CPU.

2.8 SPI Operation Using the Clock Stop Mode

This section describes how the ASP can communicate with one or more devices using the SPI protocol.

2.8.1 SPI Protocol

The SPI protocol is a master-slave configuration with one master device and one or more slave devices. The DM335 supports SPI protocol in master mode only. The interface consists of the following four signals:

- Serial data input (also referred to as Master In—Slave Out, or MISO).
- Serial data output (also referred to as Master Out—Slave In, or MOSI).
- Shift-clock (also referred to as SCK).
- Slave-enable signal (also referred to as $\overline{\text{SS}}$).

A typical SPI interface with a single slave device is shown in [Figure 33](#).

Figure 33. Typical SPI Interface

The master device controls the flow of communication by providing shift-clock and slave-enable signals. The slave-enable signal is an optional active-low signal that enables the serial data input and output of the slave device (the device not sending out the clock).

In the absence of a dedicated slave-enable (\overline{SS}) signal, communication between the master and slave is determined by the presence or absence of an active shift-clock. When the ASP is operating in SPI master mode and the \overline{SS} signal is not used by the slave SPI port, the slave device must remain enabled at all times, and multiple slaves cannot be used.

2.8.2 Clock Stop Mode

The clock stop mode of the ASP provides compatibility with the SPI protocol. When the ASP is configured in clock stop mode, the transmitter and receiver are internally synchronized, so that the ASP functions as an SPI master. The transmit clock signal (CLKX) corresponds to the serial clock signal (SCK) of the SPI protocol, while the transmit frame-synchronization signal (FSX) is used as the slave-enable (\overline{SS}) signal.

The receive clock signal (CLKR) and receive frame-synchronization signal (FSR) are not used in the clock stop mode because these signals are internally connected to their transmit counterparts, CLKX and FSX.

2.8.3 Bits Used to Enable and Configure the Clock Stop Mode

[Table 16](#) lists the bits required to configure the ASP as an SPI device. [Table 17](#) shows how the various combinations of the clock stop mode (CLKSTP) bit and the transmit clock polarity (CLKXP) bit create four possible clock stop mode configurations. The timing diagrams in [Section 2.8.4](#) show the effects of CLKSTP and CLKXP.

Table 16. Bits Used to Enable and Configure the Clock Stop Mode

Register	Bit	Description
Serial port control register (SPCR)	CLKSTP	Enables the clock stop mode and to select one of two timing variations.
Pin control register (PCR)	CLKXP	Determines the polarity of the CLKX signal.
	CLKXM	Determines whether CLKX is an input signal or an output signal (ASP as master).
Receive control register (RCR)	RPHASE	You must use a single-phase receive frame (RPHASE = 0).
	RFRLLEN1	You must use a receive frame length of 1 serial word (RFRLLEN1 = 0).
	RWDLEN1	Determines the receive packet length. RWDLEN1 must be equal to XWDLEN1 because in the clock stop mode, the ASP transmit and receive circuits are synchronized to a single clock.

Table 16. Bits Used to Enable and Configure the Clock Stop Mode (continued)

Register	Bit	Description
Transmit control register (XCR)	XPHASE	You must use a single-phase transmit frame (XPHASE = 0).
	XFRLEN1	You must use a transmit frame length of 1 serial word (XFRLEN1 = 0).
	XWDLEN1	Determines the transmit packet length. XWDLEN1 must be equal to RWDLEN1 because in the clock stop mode, the ASP transmit and receive circuits are synchronized to a single clock.

Table 17. Effects of CLKSTP and CLKXP Bits on the Clock Scheme

CLKSTP Bit in SPCR	CLKXP Bit in PCR	Clock Scheme
0 or 1	X	Clock stop mode is disabled. Clock is enabled for non-SPI mode.
		Low inactive state:
2h	0	Low inactive state without delay: The ASP transmits data on the rising edge of CLKX and receives data on the falling edge of CLKR. See Figure 34 .
3h	0	Low inactive state with delay: The ASP transmits data one-half cycle ahead of the rising edge of CLKX and receives data on the rising edge of CLKR. See Figure 35 .
		High inactive state:
2h	1	High inactive state without delay: The ASP transmits data on the falling edge of CLKX and receives data on the rising edge of CLKR. See Figure 36 .
3h	1	High inactive state with delay: The ASP transmits data one-half cycle ahead of the falling edge of CLKX and receives data on the falling edge of CLKR. See Figure 37 .

2.8.4 Clock Stop Mode Timing Diagrams

The timing diagrams for the four possible clock stop mode configurations are shown in [Figure 34](#) through [Figure 37](#). Notice that the frame-synchronization signal used in clock stop mode is active throughout the entire transmission as a slave-enable signal. Although the timing diagrams show 8-bit transfers, the packet length can be set to 8, 12, 16, 20, 24, or 32 bits per packet. The receive packet length is selected with the RWDLEN1 bits in RCR, and the transmit packet length is selected with the XWDLEN1 bits in XCR. For clock stop mode, the values of RWDLEN1 and XWDLEN1 must be the same because the ASP transmit and receive circuits are synchronized to a single clock.

Note: Even if multiple words are consecutively transferred, the CLKX signal is always stopped and the FSX signal returns to the inactive state after a packet transfer. When consecutive packet transfers are performed, this leads to a minimum idle time of two bit-periods between each packet transfer.

Figure 34. SPI Transfer with CLKSTP = 2h (no clock delay) and CLKXP = 0

- 1) If ASP is SPI master (CLKXM = 1), MOSI = DX.

- 2) If ASP is SPI master (CLKXM = 1), MISO = DR

2.8.5 Configuring a ASP for SPI Operation

Perform the following procedure to configure the ASP for SPI master:

1. Place the transmitter and receiver in reset:
 - a. To reset the transmitter, clear the transmitter reset (XRST) bit in SPCR to 0.
 - b. To reset the receiver, clear the receiver reset (RRST) bit in SPCR to 0.
2. To reset the sample rate generator, clear the sample rate generator reset (GRST) bit in SPCR to 0.
3. Program the appropriate ASP registers to configure the ASP for proper operation as an SPI master.
4. To release the sample rate generator from reset, set the sample rate generator reset (GRST) bit in SPCR to 1. Make sure that during the write to SPCR, you only modify the GRST bit; otherwise, you will modify the ASP configuration you selected in the previous step.
5. After the sample rate generator is released from reset, wait two sample rate generator clock periods for the ASP logic to stabilize.
6. Enable the transmitter and receiver:
 - a. If the CPU services the ASP transmit and receive buffers, then you can immediately enable the transmitter (XRST = 1 in SPCR) and enable the receiver (RRST = 1 in SPCR).
 - b. If the DMA controller services the ASP transmit and receive buffers, then you must first configure the DMA controller (this includes enabling the channels that service the ASP buffers). When the DMA controller is ready, set XRST = 1 and RRST = 1.
 - c. In either case, make sure you only change the XRST and RRST bits when you write to SPCR; otherwise, you will modify the bit settings you selected earlier in this procedure.
7. After the transmitter and receiver are released from reset, wait two sample rate generator clock periods for the ASP logic to stabilize.
8. If necessary, enable the frame-sync logic of the sample rate generator. After the required data acquisition setup is done (DXR is loaded with data), set the FRST bit in SPCR to 1 if an internally generated frame-sync pulse is required (that is, if the ASP is the SPI master).

2.8.6 ASP as the SPI Master

An SPI interface with the ASP used as the master is shown in Figure 38. When the ASP is configured as a master, the transmit output signal (DX) is used as the MOSI signal of the SPI protocol, and the receive input signal (DR) is used as the MISO signal. The register bit values required to configure the ASP as a master are listed in Table 18. After the table are more details about the configuration requirements.

Figure 38. ASP as the SPI Master

Table 18. Bit Values Required to Configure the ASP as an SPI Master

Register	Required Bit Setting	Description
Serial port control register (SPCR)	CLKSTP = 2h or 3h	The clock stop mode (without or with a clock delay) is selected.
Pin control register (PCR)	FSXM = 1	The FSX pin is an output pin driven according to the FSGM bit in SRGR.
	CLKXM = 1	The CLKX pin is an output pin driven by the internal sample rate generator. Because CLKSTP is equal to 2h or 3h, CLKR is driven internally by CLKX.
	SCLKME = 0	SCLKME bit is used in conjunction with the CLKSM bit in SRGR to determine the source for the input clock. The clock generated by the sample rate generator (CLKG) is derived from the ASP internal input clock.
	FSXP = 1 CLKXP = 0 or 1	The FSX pin is active low. The polarity of CLKX as seen on the CLKX pin is positive (CLKXP = 0) or negative (CLKXP = 1).
Sample rate generator register (SRGR)	CLKSM = 1	CLKSM bit is used in conjunction with the SCLKME bit in SRGR to determine the source for the input clock. The clock generated by the sample rate generator (CLKG) is derived from the ASP internal input clock.
	FSGM = 0	The transmitter drives a frame-sync pulse on the FSX pin every time data is transferred from DXR to XSR.
	CLKGDV = 0 to FFh	CLKGDV defines the divide-down value for CLKG.
Transmit control register (XCR)	XDATDLY = 1	This setting provides the correct setup time on the FSX signal, 1-bit data delay.
Receive control register (RCR)	RDATDLY = 1	This setting provides the correct setup time on the FSX signal, 1-bit data delay.

When the ASP functions as the SPI master, it controls the transmission of data by producing the serial clock signal. The clock signal on the CLKX pin is enabled only during packet transfers. When packets are not being transferred, the CLKX pin remains high or low depending on the polarity used.

For SPI master operation, the CLKX pin must be configured as an output. The sample rate generator is then used to derive the CLKX signal from the ASP internal input clock. The clock stop mode internally connects the CLKX pin to the CLKR signal so that no external signal connection is required on the CLKR pin, and both the transmit and receive circuits are clocked by the master clock (CLKX).

The data delay parameters of the ASP (XDATDLY and RDATDLY) must be set to 1 for proper SPI master operation. A data delay value of 0 or 2 is undefined in the clock stop mode.

The ASP can also provide a slave-enable (\overline{SS}) signal on the FSX pin. If a slave-enable signal is required, the FSX pin must be configured as an output, and the transmitter must be configured so that a frame-sync pulse is generated automatically each time a packet is transmitted (FSGM = 0). The polarity of the FSX pin is programmable high or low; however, in most cases the pin should be configured active-low.

When the ASP is configured as described for SPI-master operation, the bit fields for frame-sync pulse width (FWID) and frame-sync period (FPER) are overridden, and custom frame-sync waveforms are not allowed. The signal becomes active before the first bit of a packet transfer, and remains active until the last bit of the packet is transferred. After the packet transfer is complete, the FSX signal returns to the inactive state.

2.9 Interrupt Support

The ASP can send both receive and transmit interrupts to the ARM interrupt controller. For more information on the interrupt controller, refer to the *TMS320DM335 Digital Media System-on-Chip (DMSoC) ARM Subsystem Reference Guide* ([SPRUFX7](#)).

2.9.1 Interrupt Events and Requests

The RRDY and XRDY bits in SPCR indicate the ready state of the ASP receiver and transmitter, respectively. Writes and reads from the serial port can be synchronized by any of the following methods:

- Polling RRDY and XRDY bits
- Using the events sent to the EDMA controller (REVT and XEVT)
- Using the interrupts to the CPU (RINT and XINT) that the events generate

Reading DRR and writing to DXR affects RRDY and XRDY, respectively.

2.9.1.1 Interrupt Events: RINT and XINT

The receive interrupt (RINT) and transmit interrupt (XINT) signals inform the ARM CPU of changes to the serial port status. Three options exist for configuring these interrupts. These options are set by the receive/transmit interrupt mode bits (RINTM and XINTM) in SPCR. The possible values of the mode, and the configurations they represent, are:

- (R/X)INTM = 00b. Interrupt on every serial element by tracking the (R/X)RDY bits in SPCR.
- (R/X)INTM = 10b. Interrupt on detection of frame synchronization pulses. The associated portion (receiver/transmitter) of the ASP *must be out of reset*.
- (R/X)INTM = 11b. Interrupt on frame synchronization error. Note that if any of the other interrupt modes are selected, (R/X)SYNCERR may be read when servicing the interrupts to detect this condition. See [Section 2.4.5.2](#) and [Section 2.4.5.5](#) for more details on synchronization error.

2.9.1.2 Receive Ready Status: RINT and RRDY

RRDY = 1 indicates that the RBR contents have been copied to DRR and that the data can now be read by either the CPU or the EDMA controller. Once that data has been read by either the CPU, RRDY is cleared to 0. Also, at device reset or serial port receiver reset (RRST = 0), the RRDY bit is cleared to 0 to indicate that no data has been received and loaded into DRR. RRDY directly drives the ASP receive interrupt (RINT) to the CPU if RINTM = 00b (default value) in SPCR.

2.9.1.3 Transmit Ready Status: XINT and XRDY

XRDY = 1 indicates that the DXR contents have been copied to XSR and that DXR is ready to be loaded with a new data word. When the transmitter transitions from reset to non-reset (XRST transitions from 0 to 1), XRDY also transitions from 0 to 1 indicating that DXR is ready for new data. Once new data is loaded by the CPU, the XRDY bit is cleared to 0. However, once this data is copied from DXR to XSR, the XRDY bit transitions again from 0 to 1. The CPU can write to DXR although XSR has not yet been shifted out on DX. XRDY directly drives the ASP transmit interrupt (XINT) to the CPU if XINTM = 00b (default value) in SPCR.

Note: If the polling method is used to service the transmitter, the CPU should wait for one ASP bit clock (CLKX) before polling again to write the next element in DXR. This is because XRDY transitions occur based on bit clock and not CPU clock. The CPU clock is much faster and can cause false XRDY status, leading to data errors due to over-writes.

2.9.2 Interrupt Multiplexing

The total number of interrupts in the device exceeds 64, which is the maximum value of the AINTC module. Therefore, several interrupts are multiplexed and you must use the register ARM_INTMUX in the System Control Module to select the interrupt source for multiplexed interrupts. In particular, the ASP interrupts are multiplexed. For more information on the System Control Module register ARM_INTMUX, refer to the *TMS320DM335 Digital Media System-on-Chip (DMSoC) ARM Subsystem Reference Guide (SPRUFX7)*.

2.10 EDMA Event Support

2.10.1 Receive Ready Status: REVT and RRDY

RRDY = 1 indicates that the RBR contents have been copied to DRR and that the data can now be read by the EDMA controller. Once that data has been read by the EDMA controller, RRDY is cleared to 0. Also, at device reset or serial port receiver reset (RRST = 0), the RRDY bit is cleared to 0 to indicate that no data has been received and loaded into DRR. RRDY directly drives the ASP receive event to the EDMA controller (via REVT).

For detailed information on using the EDMA to read or write to the ASP, see the *TMS320DM335 DMSoC Enhanced DMA (EDMA) Controller User's Guide (SPRUFZ0)*.

2.10.2 Transmit Ready Status: XEVT and XRDY

XRDY = 1 indicates that the DXR contents have been copied to XSR and that DXR is ready to be loaded with a new data word. When the transmitter transitions from reset to non-reset (XRST transitions from 0 to 1), XRDY also transitions from 0 to 1 indicating that DXR is ready for new data. Once new data is loaded by the EDMA controller, the XRDY bit is cleared to 0. However, once this data is copied from DXR to XSR, the XRDY bit transitions again from 0 to 1. The EDMA controller can write to DXR although XSR has not yet been shifted out on DX. XRDY directly drives the transmit synchronization event to the EDMA controller (via XEVT).

Note: If the polling method is used to service the transmitter, the CPU should wait for one ASP bit clock (CLKX) before polling again to write the next element in DXR. This is because XRDY transitions occur based on bit clock and not CPU clock. The CPU clock is much faster and can cause false XRDY status, leading to data errors due to over-writes.

2.11 Power Management

The ASP can be placed in reduced power modes to conserve power during periods of low activity. The power management of the peripheral is controlled by the processor Power and Sleep Controller (PSC). The PSC acts as a master controller for power management for all of the peripherals on the device.

In order for the ASP to be placed in power-down mode by the PSC, ensure that the XRDY and RRDY flags in the serial port control register (SPCR) are cleared by performing the following steps:

1. Place the ASP in reset by clearing the XRST, RREST, FRST, and GRST bits to 0 in SPCR.
2. If EDMA is being used to service the transmitter and/or the receiver, disable the associated EDMA channels.
3. Switch the ASP clocks and frames to internal clock source:
 - a. Set the CLKSM and FSGM bits to 1 in the sample rate generator register (SRGR).
 - b. Set the CLKXM, CLKRM, FSXM, and FSRM bits to 1 in the pin control register (PCR).
 - c. Clear the SCLKME bit to 0 in PCR.
4. Bring the ASP out of reset by setting the XRST, RREST, and GRST bits to 1 in SPCR.
5. Wait for two CLKSRG cycles for proper internal synchronization.
6. Write a dummy data value to the data transmit register (DXR) in order to clear the first XRDY flag.
7. Wait for at least one ASP bit clock, since once the first dummy data value is internally copied from DXR to XSR, the XRDY flag transitions again from 0 to 1.
8. Write a second dummy data value to DXR in order to clear the second XRDY flag.
9. Check the RRDY flag in SPCR and if set to 1, read the data receive register (DRR) and discard the data to clear the RRDY flag.
10. Place the ASP in power-down mode by issuing the proper PSC commands.

Note: After waking up the ASP from a power-down mode using the proper PSC commands, remember to reconfigure the SPCR, SRGR, and PCR registers to the clock and frame combination that they were in before entering the power-down sequence and discard the two dummy data values that were used to clear the XRDY flags. If EDMA is used, re-enable the corresponding EDMA channels.

2.12 Emulation Considerations

FREE and SOFT are special emulation bits in SPCR that determine the state of the ASP when an emulation suspend event occurs in the emulator. An emulation suspend event corresponds to any type of emulator access to the ARM, such as a hardware or software breakpoint, a probe point, or a printf instruction.

Table 19 shows the effects of the FREE and SOFT bits on the response of the ASP to emulation suspend events.

Table 19. ASP Emulation Modes Selectable With the FREE and SOFT Bits of SPCR

FREE	SOFT	ASP Emulation Mode
0	0	Immediate stop mode (reset condition). The transmitter and receiver stop immediately in response to an emulation suspend event.
0	1	Soft stop mode. When an emulation suspend event occurs, the transmitter stops after completion of the current word. The receiver is not affected.
1	0 or 1	Free run mode. The transmitter and receiver continue to run when an emulation suspend event occurs.

3 Registers

Table 20 lists the memory-mapped registers for the ASP. See the device-specific data manual for the memory address of these registers. All other register offset addresses not listed in Table 20 should be considered as reserved locations and the register contents should not be modified.

The ASP control registers are accessible by the ARM CPU. You should halt the ASP before making changes to the serial port control register (SPCR), receive control register (RCR), transmit control register (XCR), and pin control register (PCR). Changes made to these registers without halting the ASP could result in an undefined state.

Table 20. ASP Registers

Offset	Acronym	Register Name	Section
-	RBR ⁽¹⁾	Receive buffer register	-
-	RSR ⁽¹⁾	Receive shift register	-
-	XSR ⁽¹⁾	Transmit shift register	-
00h	DRR ⁽²⁾⁽³⁾	Data receive register	Section 3.1
04h	DXR ⁽³⁾	Data transmit register	Section 3.2
08h	SPCR	Serial port control register	Section 3.3
0Ch	RCR	Receive control register	Section 3.4
10h	XCR	Transmit control register	Section 3.5
14h	SRGR	Sample rate generator register	Section 3.6
24h	PCR	Pin control register	Section 3.7

- (1) The RBR, RSR, and XSR are not directly accessible via the CPUs or the EDMA controller.
- (2) The CPUs and EDMA controller can only read this register; they cannot write to it.
- (3) The DRR and DXR are accessible via the CPUs or the EDMA controller.

3.1 Data Receive Register (DRR)

The data receive register (DRR) contains the value to be written to the data bus. The DRR is shown in Figure 39 and described in Table 21.

See the device-specific data manual for the memory address of these registers. Both the CPUs and the EDMA can access DRR in all the memory-mapped locations. An access to any EDMA bus location is equivalent to an access to DRR of the corresponding ASP.

Figure 39. Data Receive Register (DRR)

LEGEND: R = Read only; -n = value after reset

Table 21. Data Receive Register (DRR) Field Descriptions

Bit	Field	Value	Description
31-0	DR	0-FFFF FFFFh	Data receive register value to be written to the data bus.

3.2 Data Transmit Register (DXR)

The data transmit register (DXR) contains the value to be loaded into the data transmit shift register (XSR). The DXR is shown in [Figure 40](#) and described in [Table 22](#).

See the device-specific data manual for the memory address of these registers. DXR is accessible via the peripheral bus and via the EDMA bus. Both the CPUs and the EDMA can access DXR in all the memory-mapped locations.

Figure 40. Data Transmit Register (DXR)

LEGEND: R = Read only; -n = value after reset

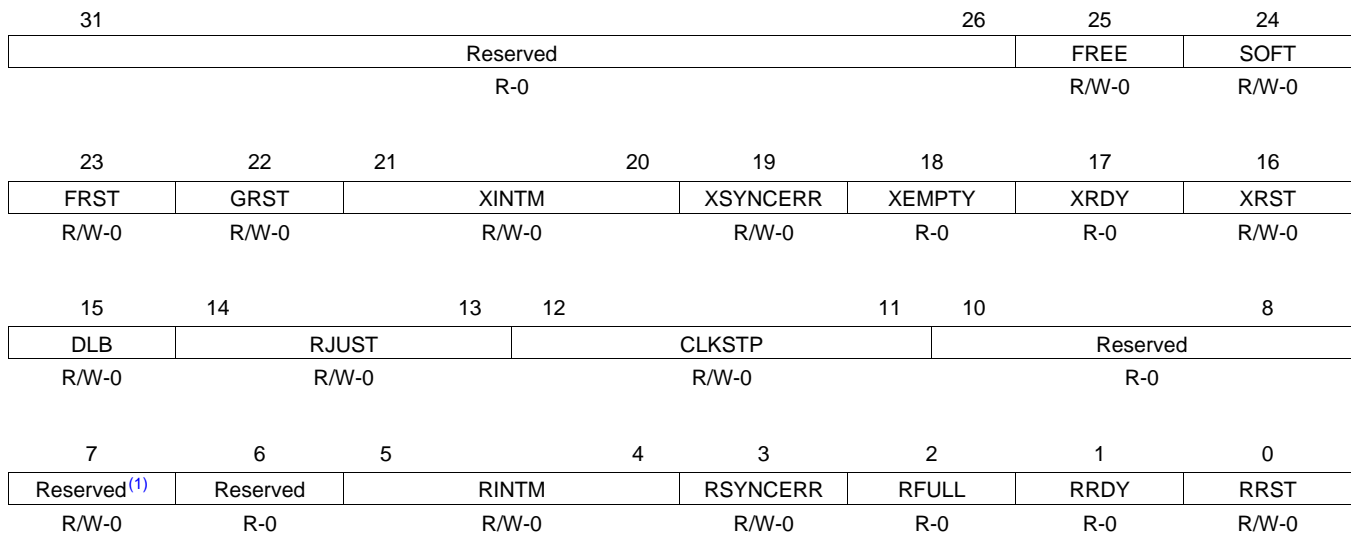

Table 22. Data Transmit Register (DXR) Field Descriptions

Bit	Field	Value	Description
31-0	DX	0-FFFF FFFFh	Data transmit register value to be loaded into the data transmit shift register (XSR).

3.3 Serial Port Control Register (SPCR)

The serial port is configured via the serial port control register (SPCR) and the pin control register (PCR). The SPCR contains ASP status control bits. The SPCR is shown in [Figure 41](#) and described in [Table 23](#).

Figure 41. Serial Port Control Register (SPCR)

LEGEND: R = Read only; R/W = Read/ Write; -n = value after reset

⁽¹⁾ If writing to this field, always write the default value of 0 to ensure proper ASP operation.

Table 23. Serial Port Control Register (SPCR) Field Descriptions

Bit	Field	Value	Description
31-26	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
25	FREE	0 1	Free-running enable mode bit. This bit is used in conjunction with SOFT bit to determine state of serial port clock during emulation halt. 0 Free-running mode is disabled. During emulation halt, SOFT bit determines operation of ASP. 1 Free-running mode is enabled. During emulation halt, serial clocks continue to run.
24	SOFT	0 1	Soft bit enable mode bit. This bit is used in conjunction with FREE bit to determine state of serial port clock during emulation halt. This bit has no effect if FREE = 1. 0 Soft mode is disabled. Serial port clock stops immediately during emulation halt, thus aborting any transmissions. 1 Soft mode is enabled. During emulation halt, serial port clock stops after completion of current transmission.
23	FRST	0 1	Frame-sync generator reset bit. 0 Frame-synchronization logic is reset. Frame-sync signal (FSG) is not generated by the sample-rate generator. 1 Frame-sync signal (FSG) is generated after (FPER + 1) number of CLKG clocks; that is, all frame counters are loaded with their programmed values.
22	GRST	0 1	Sample-rate generator reset bit. 0 Sample-rate generator is reset. 1 Sample-rate generator is taken out of reset. CLKG is driven as per programmed value in sample-rate generator register (SRGR).
21-20	XINTM	0-3h 0 1h 2h 3h	Transmit interrupt (XINT) mode bit. 0 XINT is driven by XRDY (end-of-word). 1h Reserved 2h XINT is generated by a new frame synchronization. 3h XINT is generated by XSYNCERR.
19	XSYNCERR	0 1	Transmit synchronization error bit. Writing a 1 to XSYNCERR sets the error condition when the transmitter is enabled (XRST = 1). Thus, it is used mainly for testing purposes or if this operation is desired. 0 No synchronization error is detected. 1 Synchronization error is detected.
18	XEMPTY	0 1	Transmit shift register empty bit. 0 XSR is empty. 1 XSR is not empty.
17	XRDY	0 1	Transmitter ready bit. 0 Transmitter is not ready. 1 Transmitter is ready for new data in DXR.
16	XRST	0 1	Transmitter reset bit resets or enables the transmitter. 0 Serial port transmitter is disabled and in reset state. 1 Serial port transmitter is enabled.
15	DLB	0 1	Digital loop back mode enable bit. 0 Digital loop back mode is disabled. 1 Digital loop back mode is enabled.
14-13	RJUST	0-3h 0 1h 2h 3h	Receive sign-extension and justification mode bit. 0 Right-justify and zero-fill MSBs in DRR. 1h Right-justify and sign-extend MSBs in DRR. 2h Left-justify and zero-fill LSBs in DRR. 3h Reserved

Table 23. Serial Port Control Register (SPCR) Field Descriptions (continued)

Bit	Field	Value	Description
12-11	CLKSTP	0-3h	Clock stop mode bit. In SPI mode, operates in conjunction with CLKXP bit of pin control register (PCR).
		0	Clock stop mode is disabled. Normal clocking for non-SPI mode.
		1h	Reserved
		In SPI mode with data sampled on rising edge (CLKXP = 0):	
		2h	Clock starts with rising edge without delay.
		3h	Clock starts with rising edge with delay.
		In SPI mode with data sampled on falling edge (CLKXP = 1):	
		2h	Clock starts with falling edge without delay.
		3h	Clock starts with falling edge with delay.
10-8	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
7	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect. If writing to this field, always write the default value of 0 to ensure proper ASP operation.
6	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
5-4	RINTM	0-3h	Receive interrupt (RINT) mode bit.
		0	RINT is driven by RRDY (end-of-word).
		1h	Reserved
		2h	RINT is generated by a new frame synchronization.
		3h	RINT is generated by RSYNCERR.
3	RSYNCERR		Receive synchronization error bit. Writing a 1 to RSYNCERR sets the error condition when the receiver is enabled (RRST = 1). Thus, it is used mainly for testing purposes or if this operation is desired.
		0	No synchronization error is detected.
		1	Synchronization error is detected.
2	RFULL		Receive shift register full bit.
		0	RBR is not in overrun condition.
		1	DRR is not read, RBR is full, and RSR is also full with new word.
1	RRDY		Receiver ready bit.
		0	Receiver is not ready.
		1	Receiver is ready with data to be read from DRR.
0	RRST		Receiver reset bit resets or enables the receiver.
		0	The serial port receiver is disabled and in reset state.
		1	The serial port receiver is enabled.

3.4 Receive Control Register (RCR)

The receive control register (RCR) configures parameters of the receive operations. The RCR is shown in Figure 42 and described in Table 24.

Figure 42. Receive Control Register (RCR)

31	30	24	23	21	20	19	18	17	16

15	14	8	7	5	4	3	0		
Reserved		RFRLN1		RWDLEN1		RWDREVR5		Reserved	
R-0		R/W-0		R/W-0		R/W-0		R-0	

LEGEND: R = Read only; R/ W = Read/Write; -n = value after reset

Table 24. Receive Control Register (RCR) Field Descriptions

Bit	Field	Value	Description
31	RPHASE	0 1	Receive phases bit. Single-phase frame Dual-phase frame
30-24	RFRLN2	0-7Fh 0 1h 2h ... 7Fh	(RFRLN2 + 1) specifies the receive frame length (number of words) in phase 2. 1 word in phase 2 2 words in phase 2 3 words in phase 2 ... 128 words in phase 2
23-21	RWDLEN2	0-7h 0 1h 2h 3h 4h 5h 6h-7h	Specifies the receive word length (number of bits) in phase 2. Receive word length is 8 bits. Receive word length is 12 bits. Receive word length is 16 bits. Receive word length is 20 bits. Receive word length is 24 bits. Receive word length is 32 bits. Reserved
20-19	RCOMPAND	0-3h 0 1h 2h 3h	Receive companding mode bit. Modes other than 00 are only enabled when RWDLEN1/2 bit is 000 (indicating 8-bit data). No companding, data transfer starts with MSB first. No companding, 8-bit data transfer starts with LSB first. Compand using -law for receive data. Compand using A-law for receive data.
18	RFIG	0 1	Receive frame ignore bit. Receive frame-synchronization pulses after the first pulse restarts the transfer. Receive frame-synchronization pulses after the first pulse are ignored.
17-16	RDATDLY	0-3h 0 1h 2h 3h	Receive data delay bit. 0-bit data delay 1-bit data delay 2-bit data delay Reserved
15	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.

Table 24. Receive Control Register (RCR) Field Descriptions (continued)

Bit	Field	Value	Description
14-8	RFRLLEN1	0-7Fh 0 1h 2h ... 7Fh	(RFRLLEN1 + 1) specifies the receive frame length (number of words) in phase 1. 1 word in phase 1 2 words in phase 1 3 words in phase 1 ... 128 words in phase 1
7-5	RWDLEN1	0-7h 0 1h 2h 3h 4h 5h 6h-7h	Specifies the receive word length (number of bits) in phase 1. Receive word length is 8 bits. Receive word length is 12 bits. Receive word length is 16 bits. Receive word length is 20 bits. Receive word length is 24 bits. Receive word length is 32 bits. Reserved
4	RWDREVRS	0 1	Receive 32-bit bit reversal enable bit. 32-bit bit reversal is disabled. 32-bit bit reversal is enabled. 32-bit data is received LSB first. RWDLEN1/2 bit should be set to 5h (32-bit operation); RCOMPAND bit should be set to 1h (transfer starts with LSB first); otherwise, operation is undefined.
3-0	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.

3.5 Transmit Control Register (XCR)

The transmit control register (XCR) configures parameters of the transmit operations. The XCR is shown in [Figure 43](#) and described in [Table 25](#).

Figure 43. Transmit Control Register (XCR)

23-21	XWDLEN2	0-7h 0 1h 2h 3h 4h 5h 6h-7h	Specifies the transmit word length (number of bits) in phase 2. Transmit word length is 8 bits. Transmit word length is 12 bits. Transmit word length is 16 bits. Transmit word length is 20 bits. Transmit word length is 24 bits. Transmit word length is 32 bits. Reserved
20-19	XCOMPAND	0-3h 0 1h 2h 3h	Transmit companding mode bit. Modes other than 00 are only enabled when XWDLEN1/2 bit is 000 (indicating 8-bit data). No companding, data transfer starts with MSB first. No companding, 8-bit data transfer starts with LSB first. Compand using -law for transmit data. Compand using A-law for transmit data.
18	XFIG	0 1	Transmit frame ignore bit. Transmit frame-synchronization pulses after the first pulse restarts the transfer. Transmit frame-synchronization pulses after the first pulse are ignored.
17-16	XDATDLY	0-3h 0 1h 2h 3h	Transmit data delay bit. 0-bit data delay 1-bit data delay 2-bit data delay Reserved
15	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.

Table 25. Transmit Control Register (XCR) Field Descriptions (continued)

Bit	Field	Value	Description
14-8	XFRLEN1	0-7Fh 0 1h 2h ... 7Fh	(XFRLEN1 + 1) specifies the transmit frame length (number of words) in phase 1. 1 word in phase 1 2 words in phase 1 3 words in phase 1 ... 128 words in phase 1
7-5	XWDLEN1	0-7h 0 1h 2h 3h 4h 5h 6h-7h	Specifies the transmit word length (number of bits) in phase 1. Transmit word length is 8 bits. Transmit word length is 12 bits. Transmit word length is 16 bits. Transmit word length is 20 bits. Transmit word length is 24 bits. Transmit word length is 32 bits. Reserved
4	XWDREVRS	0 1	Transmit 32-bit bit reversal feature enable bit. 32-bit bit reversal is disabled. 32-bit bit reversal is enabled. 32-bit data is transmitted LSB first. XWDLEN1/2 bit should be set to 5h (32-bit operation); XCOMPAND bit should be set to 1h (transfer starts with LSB first); otherwise, operation is undefined.
3-0	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.

3.6 Sample Rate Generator Register (SRGR)

The sample rate generator register (SRGR) controls the operation of various features of the sample rate generator. The SRGR is shown in Figure 44 and described in Table 26.

Figure 44. Sample Rate Generator Register (SRGR)

31	30	29	28	27	16
Reserved	CLKS P	CLKSM	FSGM	FPER	
R-0	R/W-0	R/W-1	R/W-0	R/W-0	
			8	7	0
FWID			CLKGDV		
R/W-0			R/W-1		

LEGEND: R/W = Read/Write; -n = value after reset

Table 26. Sample Rate Generator Register (SRGR) Field Descriptions

Bit	Field	Value	Description									
31	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.									
30	CLKSP	0	CLKS Pin Polarity									
		0	Rising edge on CLKS pin generates CLKG and FSG.									
		1	Falling edge on CLKS pin generates CLKG and FSG.									
29	CLKSM		Sample rate generator input clock mode bit. The sample rate generator can accept an input clock signal and divide it down according to CLKGDV to produce an output clock signal, CLKG. The frequency of CLKG is: $CLKG\ frequency = Input\ clock\ frequency / (CLKGDV + 1)$									
			CLKSM is used in conjunction with the SCLKME bit in the serial port control register (SPCR) to determine the source for the input clock.									
		0	A reset selects the ASP internal input clock as the input clock and forces the CLKG frequency to 1/2 the ASP internal input clock frequency. The input clock for the sample rate generator is taken from the CLKS pin or from the CLKR pin, depending on the value of the SCLKME bit of PCR as shown below:									
			<table border="1" style="margin-left: auto; margin-right: auto;"> <thead> <tr> <th>CLKSM</th> <th>SCLKME</th> <th>Input Clock for Sample Rate Generator</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">0</td> <td style="text-align: center;">0</td> <td>Signal on CLKS pin</td> </tr> <tr> <td style="text-align: center;">0</td> <td style="text-align: center;">1</td> <td>Signal on CLKR pin</td> </tr> </tbody> </table>	CLKSM	SCLKME	Input Clock for Sample Rate Generator	0	0	Signal on CLKS pin	0	1	Signal on CLKR pin
CLKSM	SCLKME	Input Clock for Sample Rate Generator										
0	0	Signal on CLKS pin										
0	1	Signal on CLKR pin										
		1	The input clock for the sample rate generator is taken from the ASP internal input clock or from the CLKX pin, depending on the value of the SCLKME bit of PCR as shown below:									
			<table border="1" style="margin-left: auto; margin-right: auto;"> <thead> <tr> <th>CLKSM</th> <th>SCLKME</th> <th>Input Clock for Sample Rate Generator</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">1</td> <td style="text-align: center;">0</td> <td>ASP internal input clock</td> </tr> <tr> <td style="text-align: center;">1</td> <td style="text-align: center;">1</td> <td>Signal on CLKX pin</td> </tr> </tbody> </table>	CLKSM	SCLKME	Input Clock for Sample Rate Generator	1	0	ASP internal input clock	1	1	Signal on CLKX pin
CLKSM	SCLKME	Input Clock for Sample Rate Generator										
1	0	ASP internal input clock										
1	1	Signal on CLKX pin										
28	FSGM		Sample-rate generator transmit frame-synchronization mode bit is only used when FSXM = 1 in PCR.									
		0	Transmit frame-sync signal (FSX) is generated on every DXR-to-XSR copy. When FSGM = 0, FWID bit and FPER bit are ignored.									
		1	Transmit frame-sync signal (FSX) is driven by the sample-rate generator frame-sync signal (FSG).									
27-16	FPER	0-FFFh	Frame period value plus 1 specifies when the next frame-sync signal becomes active. Range is 1 to 4096 sample-rate generator clock (CLKG) periods.									
15-8	FWID	0-FFh	Frame width value plus 1 specifies the width of the frame-sync pulse (FSG) during its active period.									
7-0	CLKGDV	0-FFh	Sample-rate generator clock (CLKG) divider value is used as the divide-down number to generate the required sample-rate generator clock frequency.									

3.7 Pin Control Register (PCR)

The serial port is configured via the serial port control register (SPCR) and the pin control register (PCR). The PCR contains ASP status control bits. The PCR is shown in [Figure 45](#) and described in [Table 27](#).

Figure 45. Pin Control Register (PCR)

31	Reserved						16
R-0							
15	14	13	12	11	10	9	8
Reserved	Reserved ⁽¹⁾	Reserved ⁽¹⁾	FSXM	FSRM	CLKXM	CLKRM	
R-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0
7	6	5	4	3	2	1	0
SCLKME	Reserved ⁽¹⁾	Reserved	Reserved	FSXP	FSRP	CLKXP	CLKRP
R/W-0	R-0	R/W-0	R-0	R/W-0	R/W-0	R/W-0	R/W-0

LEGEND: R = Read only; R/W = Read/Write; -n = value after reset

⁽¹⁾ If writing to this field, always write the default value of 0 to ensure proper ASP operation.

Table 27. Pin Control Register (PCR) Field Descriptions

Bit	Field	Value	Description
31-14	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
13-12	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect. If writing to this field, always write the default value of 0 to ensure proper ASP operation.
11	FSXM	0 1	Transmit frame-synchronization mode bit. 0 Frame-synchronization signal is derived from an external source. 1 Frame-synchronization signal is determined by FSGM bit in SRGR.
10	FSRM	0 1	Receive frame-synchronization mode bit. 0 Frame-synchronization signal is derived from an external source. FSR is an input pin. 1 Frame-synchronization signal is generated internally by the sample-rate generator. FSR is an output pin.
9	CLKXM	0 1	Transmit clock mode bit 0 CLKX is an input pin and is driven by an external clock. 1 CLKX is an output pin and is driven by the internal sample-rate generator.
8	CLKRM	0 1	Receive clock mode bit Digital loop back mode is disabled (DLB = 0 in SPCR): 0 CLKR is an input pin and is driven by an external clock. 1 CLKR is an output pin and is driven by the internal sample-rate generator.
		0 1	Digital loop back mode is enabled (DLB = 1 in SPCR): 0 Receive clock (not the CLKR pin) is driven by transmit clock (CLKX) that is based on CLKXM bit. CLKR pin is in high-impedance state. 1 CLKR is an output pin and is driven by the transmit clock. The transmit clock is based on CLKXM bit.

Table 27. Pin Control Register (PCR) Field Descriptions (continued)

Bit	Field	Value	Description																		
7	SCLKME	0	<p>Sample rate generator input clock mode bit. The sample rate generator can produce a clock signal, CLKG. The frequency of CLKG is:</p> $CLKG \text{ frequency} = \text{Input clock frequency} / (CLKGDV + 1)$ <p>SCLKME is used in conjunction with the CLKSM bit in the sample rate generator register (SRGR) to select the input clock.</p> <p>A reset selects the ASP internal input clock as the input clock and forces the CLKG frequency to 1/2 the ASP internal input clock frequency.</p> <p>The input clock for the sample rate generator is taken from the CLKS pin or from the ASP internal input clock, depending on the value of the CLKSM bit in SRGR as shown below:</p> <table border="1"> <thead> <tr> <th>SCLKME</th> <th>CLKSM</th> <th>Input Clock for Sample Rate Generator</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Signal on CLKS pin</td> </tr> <tr> <td>0</td> <td>1</td> <td>ASP internal input clock</td> </tr> </tbody> </table> <p>The input clock for the sample rate generator is taken from the CLKR pin or from the CLKX pin, depending on the value of the CLKSM bit in SRGR as shown below:</p> <table border="1"> <thead> <tr> <th>SCLKME</th> <th>CLKSM</th> <th>Input Clock for Sample Rate Generator</th> </tr> </thead> <tbody> <tr> <td>1</td> <td>0</td> <td>Signal on CLKR pin</td> </tr> <tr> <td>1</td> <td>1</td> <td>Signal on CLKX pin</td> </tr> </tbody> </table>	SCLKME	CLKSM	Input Clock for Sample Rate Generator	0	0	Signal on CLKS pin	0	1	ASP internal input clock	SCLKME	CLKSM	Input Clock for Sample Rate Generator	1	0	Signal on CLKR pin	1	1	Signal on CLKX pin

SCLKME	CLKSM	Input Clock for Sample Rate Generator																			
1	0	Signal on CLKR pin																			
1	1	Signal on CLKX pin																			
6	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect. If writing to this field, always write the default value of 0 to ensure proper ASP operation.																		
5-4	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.																		
3	FSXP	0	Transmit frame-synchronization polarity bit.																		
		1	Transmit frame-synchronization pulse is active low.																		
2	FSRP	0	Receive frame-synchronization polarity bit.																		
		1	Receive frame-synchronization pulse is active low.																		
1	CLKXP	0	Transmit clock polarity bit.																		
		1	Transmit data sampled on falling edge of CLKX.																		
0	CLKRP	0	Receive clock polarity bit.																		
		1	Receive data sampled on falling edge of CLKR.																		

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
