Running Bluetooth® Low Energy on CC13x2/CC26xx Without a 32 kHz Crystal

Christin Lee and Fredrik Kervel
Bluetooth low energy Solutions

ABSTRACT
This application report explains how you can configure the Bluetooth Low Energy (BLE) software stack to operate without the need for a 32 kHz crystal on the SimpleLink™ CC13x2 and CC26xx devices.

This application report explains how to configure this mode of operation, what considerations have to be taken to use the internal RC low frequency oscillator (RCOSC_LF) for the Bluetooth Low Energy peripheral and broadcast (beacon) role devices instead of the 32 kHz crystal, and what impact it has on current consumption. This document assumes the reader is familiar with the concepts described in the BLE5-Stack Users Guide and the CC13x2, CC26x2 Simplink™ Wireless MCU Technical Reference Manual.

Removing the 32 kHz crystal from a design decreases the required board space, reduces the bill of material (BOM) cost and simplifies procurement.

1 Introduction

The Bluetooth specification puts a strict requirement on the accuracy of the sleep clocks for Bluetooth Low Energy devices that are intended to enter (and stay) in a connection. The specification requires that devices have a sleep clock accuracy (SCA) that meets ± 500 ppm. For more details on the SCA requirement, see the Sleep Clock Accuracy section in the Bluetooth core specification 4.0, Volume 6, that can be downloaded from the following URL: https://www.bluetooth.com/specifications/adopted-specifications.

This sleep clock accuracy (SCA) requirement is valid for both the master and slave side of the Bluetooth Low Energy connection; however, devices such as Bluetooth Low Energy beacons do not require such accuracy as the advertising interval is intentionally varied to prevent collisions. The intention of the SCA requirement is to ensure low power consumption while maintaining flexibility in the component selection. The amount of time a slave device must stay in active RX mode, referred to as the receive window, is dependent upon the sleep clock tolerance; a less accurate sleep clock requires the receive window time to be increased, thus, increasing the average current consumption.

2 Requirements

2.1 Bluetooth Low Energy (BLE)-Stack Software Versions

Using the internal 32 kHz RC oscillator (RCOSC_LF) as Bluetooth Low Energy sleep clock requires performing a periodic, software-based calibration of the RCOSC_LF oscillator. This functionality is included in the royalty-free TI Bluetooth Low Energy software protocol stack (Bluetooth Low Energy Stack) included in SimpleLink SDK 1.0 and onwards.

2.2 Constraints

The RCOSC_LF calibration is supported for the whole CC13x2/CC26xx temperature range, but care must be taken regarding temperature gradients. To stay within the sleep accuracy requirement of ± 500 ppm, the maximum temperature change per calibration interval cannot be higher than 1°C, with the default calibration interval being 1 second.

The calibration routine will be enabled when selecting RCOSC_LF build configuration as the sleep clock source or modify the project according to the software configuration section (for applications not requiring sleep clock accuracy, the calibration can be manually disabled. For example, non-connectable advertisement used by beacon applications). The calibration will then run automatically every time when the more precise high frequency (24 or 48 MHz) oscillator starts.

To maintain ± 500 ppm accuracy, the calibration must run at least every second assuming the temperature variation does not exceed 1°C per second. In applications with effective Bluetooth Low Energy connection intervals higher than 1 s (time in Standby mode > 1 s), wake-ups must be scheduled at least every second to perform the RCOSC_LF calibration. Similarly, if the application is active for longer time periods than 1 s, the calibration must be triggered by the application. Using the supported build configurations in Section 3.2, the BLE-Stack software will automatically handle these calibration requirements.

NOTE: The 32 kHz crystal-less feature is supported on CC13x2/CC26xx wireless MCUs implementing the Bluetooth Low Energy peripheral, observer and broadcast (beacon) roles only. Thus, all central role or master devices must use the 32 kHz crystal oscillator.

3 Configuration

3.1 Hardware Configuration

No specific hardware configuration is required to run on the internal 32 kHz RC oscillator (RCOSC_LF). The 32 kHz crystal pins will be in a Hi-Z state when not used and can safely be tied to any logic level, or left unconnected.
3.2 **Software Configuration**

Refer to the BLE5-Stack Users Guide, Running the SDK on Custom Hardware - Using 32-kHz Crystal-Less Mode section, for details on SW configuration.

4 **Performance**

4.1 **Current Consumption**

Using the internal RCOSC_LF as the sleep clock has a net effect on the device current consumption as compared to board designs that utilize an external 32 kHz crystal oscillator. The difference in current consumption varies depending on the configured role of the device. For peripheral (slave) devices in a Bluetooth Low Energy connection, the current consumption will be higher when using the RCOSC_LF as compared to using an external 32 kHz crystal; however, the increase in current consumption is dependent on a number of factors. This increase is due to:

- Performing the calibration at a certain interval
- The extended receive window due to the maximum allowed sleep clock accuracy (± 500 ppm, vs. typically ± 40 ppm with a 32 kHz crystal).

During periods where the CC13x2/CC26xx is advertising (for example, as a beacon or waiting for a connection request) or in standby (while idle), current consumption using the internal RCOSC_LF will be less (better) than using a 32 kHz crystal oscillator.

The calibration process itself takes approximately 1 ms, and for a typical Bluetooth Low Energy connection event the calibration will happen in the background while the radio operates. In most cases, the added current consumption from performing the calibration will thus be negligible. In configurations with longer effective Bluetooth Low Energy connection intervals, that is the connection interval with the maximum slave latency applied is greater than 1 second, there will be additional power consumption because the device has to wake up from standby (sleep) between the connection events to perform the RCOSC_LF calibration. In a board design that uses a 32 kHz crystal, these calibration wakeups would not be required.
The average current consumption using the 32 kHz crystal as compared to using the internal RCOSC_LF for some Bluetooth Low Energy effective connection intervals can be seen in Table 1 and Figure 1. To get actual current consumption for any given configuration, follow the measurement procedure in Measuring CC13xx and CC26xx current consumption.

5 **Recommendations**

Use of the 32 kHz crystal-less feature should be considered for the following Bluetooth Low Energy operating conditions:

- Where the lowest possible BOM cost is desired or when board layout space is limited.
- Peripheral role devices (slave) that maintain short (fast) connection intervals or enter Bluetooth Low Energy connections infrequently and remain idle or advertising most of the time. Example devices include door locks, light bulbs, blood glucose meters (BGMs) and fitness/activity trackers.
- Beacon or broadcast role devices. These devices do not typically form connections and spend most of the time performing Bluetooth Low Energy advertising. These devices will achieve better (lower) current consumption with the RCOSC_LF than using an external 32 kHz crystal.
