7 Detailed Description

7.1 Overview

The LMR436x0-Q1 is a wide input, low-quiescent current, high-performance regulator that can operate over a wide range of duty ratio and switching frequencies, including sub-AM band at 400kHz and above AM band at 2.2MHz. During wide input transients, if the minimum on time or the minimum off time cannot support the desired duty ratio at the higher switching frequency settings, the switching frequency is reduced automatically, allowing the LMR436x0-Q1 to maintain the output voltage regulation. With an internally compensated design optimized for minimal output capacitors, the system design process with the LMR436x0-Q1 is simplified significantly compared to other buck regulators available in the market.

The LMR436x0-Q1 is designed to minimize external component cost and design size while operating in all demanding automotive environments. The LMR436x0-Q1 family includes variants that can be set up to operate over a wide switching frequency range, from 200kHz to 2.2MHz, with the correct resistor selection from the RT pin to ground. To further reduce system cost, the PGOOD output feature with built-in delayed release allows the elimination of the reset supervisor in many applications.

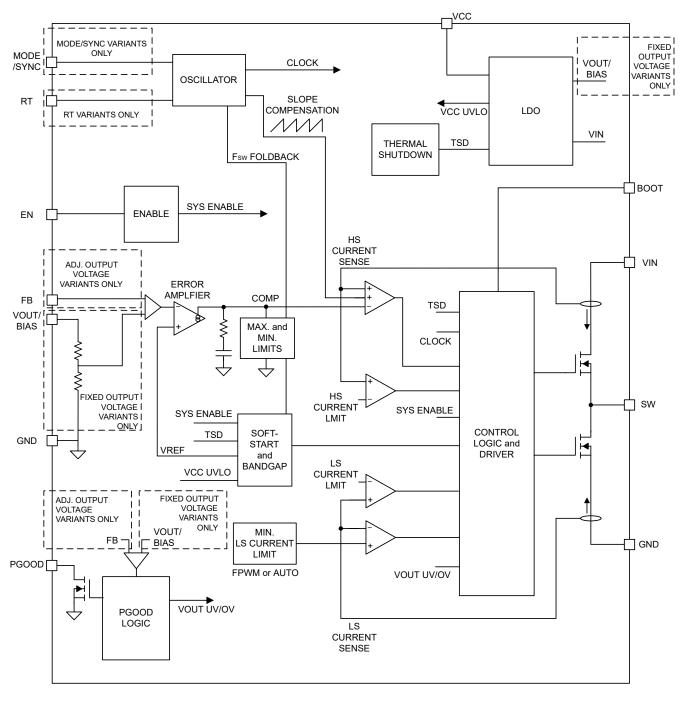

The LMR436x0-Q1 family is designed to reduce EMI/EMC emissions. The design includes a dual random spread spectrum switching frequency dithering scheme, has no bond-wire flip-chip on the lead (HotRod) package, and is available with the MODE/SYNC feature (select variants), allowing synchronization to an external clock, when available. Together, these features eliminate the need for any common-mode choke or shielding or any elaborate input filter design scheme, greatly reducing the complexity and cost of the EMI/EMC mitigation measures.

The LMR436x0-Q1 comes in an ultra-small 2mm × 2mm QFN package with wettable flanks, allowing for quick optical inspection along with specially designed corner anchor pins for reliable board level solder connections.

7.2 Functional Block Diagram

7.3 Feature Description

7.3.1 Enable, Start-Up, and Shutdown

Voltage at the EN pin controls the start-up or remote shutdown of the LMR436x0-Q1 family of devices. The part stays shut down as long as the EN pin voltage is less than $V_{EN-WAKE} = 0.5V$. During shutdown, the input current drawn by the device typically drops down to $0.25\mu A$ ($V_{IN} = 13.5V$). With the voltage at the EN pin greater than $V_{EN-WAKE}$, the device enters device standby mode and the internal LDO powers up to generate VCC. As the EN voltage increases further, approaching $V_{EN-VOUT}$, the device finally starts to switch, entering start-up mode with a soft start. During the device shutdown process, when the EN input voltage measures less than ($V_{EN-VOUT} - V_{EN-HYST}$), the regulator stops switching and re-enters device standby mode. Any further decrease in the EN pin voltage, below $V_{EN-WAKE}$, and the device is then firmly shut down. The high-voltage compliant EN input pin can be connected directly to the V_{IN} input pin if remote precision control is not needed. The EN input pin must not be allowed to float. The various EN threshold parameters and the values are listed in *Electrical Characteristics*. $\boxed{2}$ 7-2 shows the precision enable behavior and $\boxed{2}$ 7-3 shows a typical remote EN start-up waveform in an application. After EN goes high, after a delay of about 2.5ms, the output voltage begins to rise with a soft start and reaches close to the final value in about 3.5ms (t_{ss}). After a delay of about 2.5ms (t_{PGOOD_ACT}), the PGOOD flag goes high. During start-up, the device is not allowed to enter FPWM mode until the soft-start time has elapsed. This time is measured from the rising edge of EN. Check t = 0.2.2.9 for component selection.

7.3.2 External CLK SYNC (with MODE/SYNC)

It is often desirable to synchronize the operation of multiple regulators in a single system, resulting in a well-defined system level performance. The select variants in the LMR436x0-Q1 with the MODE/SYNC pin allow the power designer to synchronize the device to a common external clock. The LMR436x0-Q1 implements an in-phase locking scheme, where the rising edge of the clock signal, provided to the MODE/SYNC pin of the LMR436x0-Q1, corresponds to the turning on of the high-side device. The external clock synchronization is implemented using a phase locked loop (PLL), eliminating any large glitches. The external clock fed into the LMR436x0-Q1 replaces the internal free-running clock, but does not affect any frequency foldback operation. Output voltage continues to be well-regulated. The device remains in FPWM mode and operates in CCM for light loads when synchronization input is provided.

The MODE/SYNC input pin in the LMR436x0-Q1 can operate in one of three selectable modes:

- Auto mode: Pulse frequency modulation (PFM) operation is enabled during light load and diode emulation prevents reverse current through the inductor. See セクション 7.4.3.2 for more details.
- FPWM mode: In FPWM mode, diode emulation is disabled, allowing current to flow backwards through the inductor. This allows operation at full frequency even without load current. See セクション 7.4.3.3 for more details.
- SYNC mode: The internal clock locks to an external signal applied to the MODE/SYNC pin. As long as output
 voltage can be regulated at full frequency and is not limited by minimum off time or minimum on time, clock
 frequency is matched to the frequency of the signal applied to the MODE/SYNC pin. While the device is in
 SYNC mode, it operates as though in FPWM mode: diode emulation is disabled, allowing the frequency
 applied to the MODE/SYNC pin to be matched without a load.

7.3.2.1 Pulse-Dependent MODE/SYNC Pin Control

Most systems that require more than a single mode of operation from the LMR436x0-Q1 are controlled by digital circuitry such as a microprocessor. These systems can generate dynamic signals easily but have difficulty generating multi-level signals. Pulse-dependent MODE/SYNC pin control is useful with these systems. To initiate pulse-dependent MODE/SYNC pin control, a valid sync signal must be applied. 表 7-1 shows a summary of the pulse dependent mode selection settings.

表 7-1. Pulse-Dependent Mode Selection Settings

MODE/SYNC INPUT	MODE
> V _{MODE_H}	FPWM with spread spectrum factory setting
< V _{MODE_L}	Auto mode with spread spectrum factory setting
Synchronization Clock	SYNC mode

 \boxtimes 7-4 shows the transition between auto mode and FPWM mode while in pulse-dependent MODE/SYNC control. The LMR436x0-Q1 transitions to a new mode of operation after the time, t_{MODE} . \boxtimes 7-4 and \boxtimes 7-5 show the details.

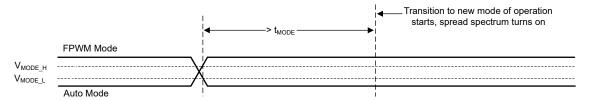

図 7-4. Transition from Auto Mode and FPWM Mode

If MODE/SYNC voltage remains constant longer than t_{MODE} , the LMR436x0-Q1 enters either auto mode or FPWM mode with spread spectrum turned on (if factory setting is enabled) and MODE/SYNC continues to operate in pulse-dependent scheme.

7.3.3 Adjustable Switching Frequency (with RT)

The select variants in the LMR436x0-Q1 family with the RT pin allow the power designers to set any desired operating frequency between 200kHz and 2.2MHz in the applications. See 区 7-7 to determine the resistor value needed for the desired switching frequency. The RT pin and the MODE/SYNC pin variants share the same pin location. The power supply designer can either use the RT pin variant and adjust the switching frequency of operation as warranted by the application or use the MODE/SYNC variant and synchronize to an external clock signal. See 表 7-2 for selection on programming the RT pin.

表 7-2. RT Pin Setting

7.3.4 Power-Good Output Operation

The power-good feature using the PGOOD pin of the LMR436x0-Q1 can be used to reset a system microprocessor whenever the output voltage is out of regulation. This open-drain output remains low under device fault conditions, such as current limit and thermal shutdown, as well as during normal start-up. A glitch

filter prevents false flag operation for any short duration excursions in the output voltage, such as during line and load transients. Output voltage excursions lasting less than t_{RESET_FILTER} do not trip the power-good flag. Power-good operation can best be understood in reference to \boxtimes 7-8. $\not\equiv$ 7-3 gives a more detailed breakdown of the PGOOD operation. Here, $V_{PGD_{UV}}$ is defined as the PGD_{UV} scaled version of V_{OUT} (target regulated output voltage) and $V_{PGD_{HYST}}$ as the PGD_{HYST} scaled version of V_{OUT} , where both PGD_{UV} and PGD_{HYST} are listed in *Electrical Characteristics*. During the initial power up, a total delay of 6 ms (typical) is encountered from the time $V_{EN-VOUT}$ is triggered to the time that the power-good is flagged high. This delay only occurs during the device start-up and is not encountered during any other normal operation of the power-good function. When EN is pulled low, the power-good flag output is also forced low. With EN low, power-good remains valid as long as the input voltage ($V_{PGD-VAL}$ is \geq 1.5V (maximum)).

The power-good output scheme consists of an open-drain n-channel MOSFET, which requires an external pullup resistor connected to a suitable logic supply. It can also be pulled up to either V_{CC} or V_{OUT} through an appropriate resistor, as desired. If this function is not needed, the PGOOD pin can be open or grounded. Limit the current into this pin to $\leq 4\text{mA}$.

表 7-3. Fault Conditions for PGOOD (Pull Low)

7.3.5 Internal LDO, VCC, and VOUT/FB Input

The LMR436x0-Q1 uses the internal LDO output and the VCC pin for all internal power supply. The VCC pin draws power either from the V_{IN} (in adjustable output variants) or the VOUT/FB (in fixed-output variants). In the fixed output variants, after the LMR436x0-Q1 is active but has yet to regulate, the VCC rail continues to draw power from the input voltage, V_{IN} , until the VOUT/FB voltage reaches > 3.3V (or when the device has reached steady-state regulation post the soft start). The VCC rail typically measures 3.3V in both adjustable and fixed output variants. During start-up, VCC momentarily exceeds the normal operating voltage, then drops to the normal operating voltage.

7.3.6 Bootstrap Voltage and V_{BOOT-UVLO} (BOOT Terminal)

The high-side switch driver circuit requires a bias voltage higher than VIN to make sure the HS switch is turned ON. The capacitor connected between BOOT and SW works as a charge pump to boost voltage on the BOOT terminal to (SW+VCC). The boot diode is integrated on the LMR436x0-Q1 die to minimize physical design size. TI recommends a 100nF capacitor rated for 10V or higher for CBOOT. The BOOT rail has a UVLO setting. This UVLO has a threshold of $V_{\rm BOOT-UVLO}$ and is typically set at 2.1V. If the CBOOT capacitor is not charged above this voltage with respect to the SW pin, then the part initiates a charging sequence, turning on the low-side switch before attempting to turn on the high-side device.

7.3.7 Output Voltage Selection

In the LMR436x0-Q1 family, an adjustable output or fixed output voltage option is configurable for every device variant (see $\forall \mathcal{D} \supset \exists \mathcal{V}$ 4). For an adjustable output, the user needs an external resistor divider connection between the output voltage node, the device FB pin, and the system GND, as shown in \boxtimes 7-9. The adjustable output voltage operation uses a 1V internal reference voltage. Refer to section $\forall \mathcal{D} \supset \exists \mathcal{V}$ 8.2.2.2.1 for more details on how to adjust the output voltage.

When using the fixed-output configuration from the LMR436x0-Q1 family, simply connect the FB pin (identified as VOUT/FB pin for fixed-output variants in the rest of the data sheet) to the system output voltage node. See セクション 4 for more details.

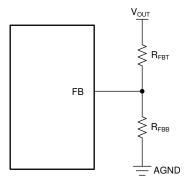

図 7-9. Setting Output Voltage for Adjustable Output Variant

7.3.8 Spread Spectrum

In the LMR436x0-Q1 family of devices, spread spectrum is a factory option. To find which parts have spread spectrum enabled, see the *Device Comparison Table*.

Spread spectrum eliminates peak emissions at specific frequencies by spreading these peaks across a wider range of frequencies than a part with fixed-frequency operation. The LMR436x0-Q1 implements a modulation pattern designed to reduce low frequency-conducted emissions from the first few harmonics of the switching frequency. The pattern can also help reduce the higher harmonics that are more difficult to filter, which can fall in the FM band. These harmonics often couple to the environment through electric fields around the switch node and inductor. The LMR436x0-Q1 uses a spread of frequencies which can spread energy smoothly across the FM and TV bands. The device implements dual random spread spectrum (DRSS). DRSS is a combination of a triangular frequency spreading pattern and pseudorandom frequency hopping. The combination allows the spread spectrum to be very effective at spreading the energy at the following:

- · Fundamental switching harmonic with slow triangular pattern
- · High frequency harmonics with additional pseudo-random jumps at the switching frequency

The advantage of DRSS is the equivalent harmonic attenuation in the upper frequencies with a smaller fundamental frequency deviation. This reduces the amount of input current and output voltage ripple that is introduced at the modulating frequency. Additionally, the LMR436x0-Q1 also allows the user to further reduce the output voltage ripple caused by the spread spectrum modulating pattern.

The spread spectrum is only available while the clock of the device is free running at the natural frequency. Any of the following conditions overrides spread spectrum, turning it off:

- The clock is slowed due to operation at low-input voltage this is operation in dropout.
- The clock is slowed under light load in auto mode. Note that if you are operating in FPWM mode, spread spectrum can be active, even if there is no load.
- The clock is slowed due to high input to output voltage ratio. This mode of operation is expected if on time reaches minimum on time. See the *Electrical Characteristics*.
- · The clock is synchronized with an external clock.

7.3.9 Soft Start and Recovery from Dropout

When designing with the LMR436x0-Q1, slow rise in output voltage due to recovery from dropout and soft start must be considered as a two separate operating conditions, as shown in ☒ 7-10 and ☒ 7-11. Soft start is triggered by any of the following conditions:

- Power is applied to the VIN pin of the device, releasing undervoltage lockout.
- EN is used to turn on the device.
- Recovery from shutdown due to overtemperature protection

After soft start is triggered, the IC takes the following actions:

- The reference used by the IC to regulate output voltage is slowly ramped up. The net result is that output voltage, if previously 0V, takes t_{SS} to reach 90% of the desired value.
- Operating mode is set to auto mode of operation, activating the diode emulation mode for the low-side MOSFET. This allows start-up without pulling the output low. This is true even when there is a voltage already present at the output during a pre-bias start-up.

図 7-10. Soft Start With and Without Pre-bias Voltage

7.3.9.1 Recovery from Dropout

Any time the output voltage falls more than a few percent, output voltage ramps up slowly. This condition, called graceful recovery from dropout in this document, differs from soft start in two important ways:

- The reference voltage is set to approximately 1% above what is needed to achieve the existing output voltage.
- If the device is set to FPWM, the device continues to operate in that mode during the recovery from dropout. If output voltage were to suddenly be pulled up by an external supply, the LMR436x0-Q1 can pull down on the output. Note that all protections that are present during normal operation are in place, preventing any catastrophic failure if output is shorted to a high voltage or ground.

Whether output voltage falls due to high load or low input voltage, after the condition that causes output to fall below the set point is removed, the output climbs at the same speed as during start-up. \boxtimes 7-12 shows an example of this behavior.

7.3.10 Current Limit and Short Circuit

The LMR436x0-Q1 is protected from overcurrent conditions by cycle-by-cycle current limiting on both high-side (HS) and low-side (LS) MOSFETs.

High-side MOSFET overcurrent protection is implemented by the typical peak-current mode control scheme. The HS switch current is sensed when the HS is turned on after a short blanking time. The HS switch current is compared to either the minimum of a fixed current set point or the output of the internal error amplifier loop minus the slope compensation every switching cycle. Because the output of the internal error amplifier loop has a maximum value and slope compensation increases with duty cycle, HS current limit decreases with increased duty factor if duty factor is typically above 35%.

When the LS switch is turned on, the current going through it is also sensed and monitored. Like the high-side device, the low-side device has a turn-off commanded by the internal error amplifier loop. In the case of the low-side device, turn-off is prevented if the current exceeds this value, even if the oscillator normally starts a new switching cycle. Also like the high-side device, there is a limit on how high the turn-off current is allowed to be. This is called the low-side current limit, I_{VALMAX}. If the LS current limit is exceeded, the LS MOSFET stays on and the HS switch is not to be turned on. The LS switch is turned off after the LS current falls below this limit and the HS switch is turned on again as long as at least one clock period has passed since the last time the HS device has turned on.

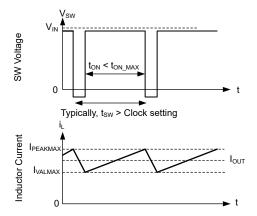

図 7-13. Current Limit Waveforms

Because the current waveform assumes values between I_{PEAKMAX} and I_{VALMAX}, the maximum output current is very close to the average of these two values unless duty factor is very high. After operating in current limit, hysteretic control is used and current does not increase as output voltage approaches zero.

If duty factor is very high, current ripple must be very low to prevent instability. Because current ripple is low, the part is able to deliver full current. The current delivered is very close to I_{VALMAX} .

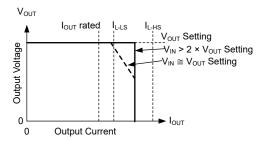

図 7-14. Output Voltage Versus Output Current

資料に関するフィードバック(ご意見やお問い合わせ)を送信

Under most conditions, current is limited to the average of $I_{PEAKMAX}$ and I_{VALMAX} . If input voltage is low, current can be limited to approximately I_{VALMAX} . Also note that the maximum output current does not exceed the average of $I_{PEAKMAX}$ and I_{VALMAX} . After the overload is removed, the part recovers as though in soft start.

7.3.11 Thermal Shutdown

Thermal shutdown limits total power dissipation by turning off the internal switches when the device junction temperature exceeds 168°C (typical). Thermal shutdown does not trigger below 158°C (minimum). After thermal shutdown occurs, hysteresis prevents the part from switching until the junction temperature drops to approximately 153°C (typical). When the junction temperature falls below 153°C (typical), the LMR436x0-Q1 attempts another soft start.

While the LMR436x0-Q1 is shut down due to high junction temperature, power continues to be provided to VCC. To prevent overheating due to a short circuit applied to VCC, the LDO that provides power for VCC has reduced current limit while the part is disabled due to high junction temperature. The LDO only provides a few milliamperes during thermal shutdown.

7.3.12 Input Supply Current

The LMR436x0-Q1 is designed to have very low input supply current when regulating light loads. This is achieved by powering much of the internal circuitry from the output. The VOUT/FB pin in the fixed-output voltage variants is the input to the LDO that powers the majority of the control circuits. By connecting the VOUT/FB input pin to the output node of the regulator, a small amount of current is drawn from the output. This current is reduced at the input by the ratio of V_{OUT}/V_{IN} as described in $\vec{\pm}$ 2.

$$I_{QVIN} = I_Q + I_{EN} + I_{BIAS} \times \frac{V_{OUT}}{\eta_{eff} \times V_{IN}}$$
 (2)

where

- I_{QVIN} is the total standby (switching) current consumed by the operating (switching) buck converter when unloaded.
- I_Q is the current drawn from the V_{IN} terminal.
- I_{BIAS} is bias current drawn by the BIAS LDO.
- η_{eff} is the light-load efficiency of the buck converter with I_{QVIN} removed from the input current of the buck converter. η_{eff} = 0.8 is a conservative value that can be used under normal operating conditions.

7.4 Device Functional Modes

7.4.1 Shutdown Mode

The EN pin provides electrical ON and OFF control of the device. When the EN pin voltage is below 0.7V (typical), both the converter and the internal LDO have no output voltage and the part is in shutdown mode. In shutdown mode, the guiescent current drops to typically 250nA.

7.4.2 Standby Mode

The internal LDO has a lower EN threshold than the output of the converter. When the EN pin voltage is above 1V (maximum) and below the precision enable threshold for the output voltage, the internal LDO regulates the VCC voltage at 3.3V typical. The internal power MOSFETs of the SW node remain off unless the voltage on EN pin goes above the precision enable threshold. The LMR436x0-Q1 also employs UVLO protection.

7.4.3 Active Mode

The LMR436x0-Q1 is in active mode whenever the EN pin is above $V_{EN-VOUT}$, V_{IN} is high enough to satisfy V_{INMIN} , and no other fault conditions are present. The simplest way to enable the operation is to connect the EN pin to V_{IN} , which allows self start-up when the applied input voltage exceeds the minimum V_{INMIN} .

In active mode, depending on the load current, input voltage, and output voltage, the LMR436x0-Q1 is in one of five modes:

- Continuous conduction mode (CCM) with fixed switching frequency when load current is above half of the inductor current ripple
- · Auto mode Light Load Operation: PFM when switching frequency is decreased at very light load
- FPWM mode Light Load Operation: Continuous conduction mode (CCM) when the load current is lower than half of the inductor current ripple
- Minimum on time: At high input voltage and low output voltages, the switching frequency is reduced to maintain regulation
- Dropout mode: When switching frequency is reduced to minimize voltage dropout

7.4.3.1 CCM Mode

The following operating description of the LMR436x0-Q1 refers to $\forall D \forall \exists \forall T$.2 and to the waveforms in \boxtimes 7-15. In CCM, the LMR436x0-Q1 supplies a regulated output voltage by turning on the internal high-side (HS) and low-side (LS) switches with varying duty cycle (D). During the HS switch on time, the SW pin voltage, V_{SW} , swings up to approximately V_{IN} , and the inductor current, i_L , increases with a linear slope. The HS switch is turned off by the control logic. During the HS switch off time, t_{OFF} , the LS switch is turned on. Inductor current discharges through the LS switch, which forces the V_{SW} to swing below ground by the voltage drop across the LS switch. The converter loop adjusts the duty cycle to maintain a constant output voltage. D is defined by the on time of the HS switch over the switching period:

$$D = T_{ON} / T_{SW}$$
 (3)

In an ideal buck converter where losses are ignored, D is proportional to the output voltage and inversely proportional to the input voltage:

$$D = V_{OUT} / V_{IN}$$
 (4)

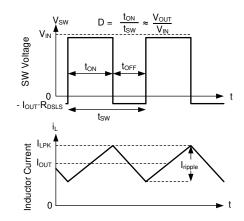

図 7-15. SW Voltage and Inductor Current Waveforms in Continuous Conduction Mode (CCM)

7.4.3.2 Auto Mode – Light-Load Operation

The LMR436x0-Q1 can have two behaviors while lightly loaded. One behavior, called auto mode operation, allows for seamless transition between normal current mode operation while heavily loaded and highly efficient light-load operation. The other behavior, called FPWM mode, maintains full frequency even when unloaded. Which mode the LMR436x0-Q1 operates in depends on which variant from this family is selected. Note that all parts operate in FPWM mode when synchronizing frequency to an external signal.

The light-load operation is employed in the LMR436x0-Q1 only in auto mode. The light load operation employs two techniques to improve efficiency:

- Diode emulation, which allows DCM operation. See 🗵 7-16.
- Frequency reduction. See

 ▼ 7-16.

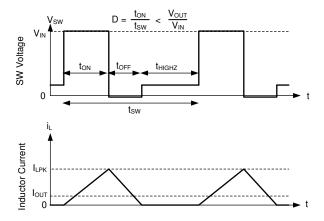

Note that while these two features operate together to improve light load efficiency, they operate independently.

7.4.3.2.1 Diode Emulation

Diode emulation prevents reverse current through the inductor which requires a lower frequency needed to regulate given a fixed peak inductor current. Diode emulation also limits ripple current as frequency is reduced. With a fixed peak current, as output current is reduced to zero, frequency must be reduced to near zero to maintain regulation.

資料に関するフィードバック(ご意見やお問い合わせ)を送信

Copyright © 2024 Texas Instruments Incorporated

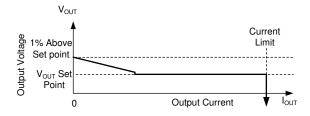

In auto mode, the low-side device is turned off after SW node current is near zero. As a result, after output current is less than half of what inductor ripple is in CCM, the part operates in DCM which is equivalent to the statement that diode emulation is active.

図 7-16. PFM Operation

The LMR436x0-Q1 has a minimum peak inductor current setting (see I_{PEAKMIN} in *Electrical Characteristics*) while in auto mode. After current is reduced to a low value with fixed input voltage, on time is constant. Regulation is then achieved by adjusting frequency. This mode of operation is called PFM mode regulation.

7.4.3.2.2 Frequency Reduction

The LMR436x0-Q1 reduces frequency whenever output voltage is high. This function is enabled whenever the internal error amplifier compensation output, COMP, an internal signal, is low and there is an offset between the regulation set point of VOUT/FB and the voltage applied to VOUT/FB. The net effect is that there is larger output impedance while lightly loaded in auto mode than in normal operation. Output voltage must be approximately 1% high when the part is completely unloaded.

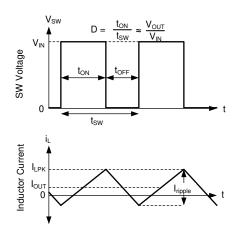

In auto mode, after output current drops below approximately 1/10th the rated current of the part, output resistance increases so that output voltage is 1% high while the buck is completely unloaded.

図 7-17. Steady State Output Voltage Versus Output Current in Auto Mode

In PFM operation, a small DC positive offset is required on the output voltage to activate the PFM detector. The lower the frequency in PFM, the more DC offset is needed on V_{OUT} . If the DC offset on V_{OUT} is not acceptable, a dummy load at V_{OUT} or FPWM mode can be used to reduce or eliminate this offset.

7.4.3.3 FPWM Mode - Light-Load Operation

In FPWM mode, frequency is maintained while lightly loaded. To maintain frequency, a limited reverse current is allowed to flow through the inductor. Reverse current is limited by reverse current limit circuitry, see *Electrical Characteristics* for reverse current limit values.

In FPWM mode, Continuous Conduction (CCM) is possible even if I_{OUT} is less than half of I_{ripple}.

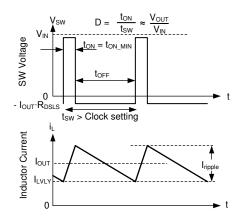

図 7-18. FPWM Mode Operation

For all devices, in FPWM mode, frequency reduction is still available if output voltage is high enough to command minimum on time even while lightly loaded, allowing good behavior during faults which involve output being pulled up.

7.4.3.4 Minimum On-Time (High Input Voltage) Operation

The LMR436x0-Q1 continues to regulate output voltage even if the input-to-output voltage ratio requires an on time less than the minimum on time of the chip with a given clock setting. This is accomplished using valley current control. At all times, the compensation circuit dictates both a maximum peak inductor current and a maximum valley inductor current. If for any reason, valley current is exceeded, the clock cycle is extended until valley current falls below that determined by the compensation circuit. If the converter is not operating in current limit, the maximum valley current is set above the peak inductor current, preventing valley control from being used unless there is a failure to regulate using peak current only. If the input-to-output voltage ratio is too high, such that the inductor current peak value exceeds the peak command dictated by compensation, the high-side device cannot be turned off quickly enough to regulate output voltage. As a result, the compensation circuit reduces both peak and valley current. After a low enough current is selected by the compensation circuit, valley current matches that being commanded by the compensation circuit. Under these conditions, the low-side device is kept on and the next clock cycle is prevented from starting until inductor current drops below the desired valley current. Because on time is fixed at the minimum value, this type of operation resembles that of a device using a Constant On-Time (COT) control scheme; see \boxtimes 7-19.

In valley control mode, minimum inductor current is regulated, not peak inductor current.

図 7-19. Valley Current Mode Operation

7.4.3.5 Dropout

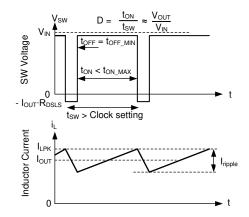

Dropout operation is defined as any input-to-output voltage ratio that requires frequency to drop to achieve the required duty cycle. At a given clock frequency, duty cycle is limited by minimum off time. After this limit is reached as shown in \boxtimes 7-21 if clock frequency was to be maintained, the output voltage falls. Instead of allowing the output voltage to drop, the LMR436x0-Q1 extends the high-side switch on time past the end of the clock cycle until the needed peak inductor current is achieved. The clock is allowed to start a new cycle after peak inductor current is achieved or after a pre-determined maximum on time, t_{ON-MAX} , of approximately 9μ s passes. As a result, after the needed duty cycle cannot be achieved at the selected clock frequency due to the existence of a minimum off time, frequency drops to maintain regulation. As shown in \boxtimes 7-20, if input voltage is low enough so that output voltage cannot be regulated even with an on time of t_{ON-MAX} , output voltage drops to slightly below the input voltage by V_{DROP} . For additional information on recovery from dropout, refer to \boxtimes 7-11.

Output voltage and frequency versus input voltage: If there is little difference between input voltage and output voltage setting, the IC reduces frequency to maintain regulation. If input voltage is too low to provide the desired output voltage at approximately 110kHz, input voltage tracks output voltage.

図 7-20. Frequency and Output Voltage in Dropout

8.1 Application Information

The LMR436x0-Q1 step-down DC-to-DC converters are typically used to convert a higher DC voltage to a lower DC voltage. LMR43620-Q1 supports a maximum output current of 2A while the LMR43610-Q1 supports a maximum output current of 1A. The following design procedure can be used to select components for the LMR43620-Q1. The design procedure can also be used to select components for the LMR43610-Q1 by limiting the maximum output current to 1A.

注

All of the capacitance values given in the following application information refer to effective values unless otherwise stated. The effective value is defined as the actual capacitance under DC bias and temperature, not the rated or nameplate values. Use high-quality, low-ESR, ceramic capacitors with an X7R or better dielectric throughout. All high value ceramic capacitors have a large voltage coefficient in addition to normal tolerances and temperature effects. Under DC bias the capacitance drops considerably. Large case sizes and higher voltage ratings are better in this regard. To help mitigate these effects, multiple capacitors can be used in parallel to bring the minimum effective capacitance up to the required value. This can also ease the RMS current requirements on a single capacitor. A careful study of bias and temperature variation of any capacitor bank must be made to make sure that the minimum value of effective capacitance is provided.

8.2.1 Design Requirements

セクション 8.2.2 provides a detailed design procedure based on 表 8-3.

表 8-3. Detailed Design Parameters

DESIGN PARAMETER	EXAMPLE VALUE		
Input voltage	12V, (4V to 36V)		
Output voltage	3.3V		
Maximum output current	0A to 2A		
Switching frequency	2200kHz		

8.2.2 Detailed Design Procedure

The following design procedure applies to 図 8-1 and 表 8-2.

8.2.2.1 Choosing the Switching Frequency

The choice of switching frequency is a compromise between conversion efficiency and overall design size. Lower switching frequency implies reduced switching losses and usually results in higher system efficiency. However, higher switching frequency allows the use of smaller inductors and output capacitors, hence, a more compact design. For this example, 2200kHz is used.

8.2.2.2 Setting the Output Voltage

The VOUT/FB pin of the device can be either connected directly to the output capacitor or the mid point of a feedback resistor divider. When connected directly to the output capacitor, the device operates as a fixed output option. The 3.3V or 5V fixed output options are factory trimmed and are unique to a specific device. See セクション 4 for the selection of fixed output voltage versions.

8.2.2.2.1 FB for Adjustable Output

If other voltages are desired, the VOUT/FB pin can be connected to a feedback resistor divider network to set the output voltage. The divider network is comprised of R_{FBT} and R_{FBB} , and closes the loop between the output voltage and the converter. The converter regulates the output voltage by holding the voltage on the FB pin equal to the internal reference voltage, V_{REF} . The converter determines whether fixed output voltage or adjustable output voltage is required by sensing the resistance of the feedback path during start-up. To make sure that the converter regulates to the desired output voltage, the typical minimum value for the parallel combination of R_{FBT} and R_{FBB} is $5k\Omega$ while the typical maximum value is $10k\Omega$ as shown in \pm 5. \pm 6 can be used as a starting point to determine the value of R_{FBT} . Reference \pm 8-4 for a list of acceptable resistor values for various output voltages.

$$5 k\Omega < R_{FBT} | |R_{FBB} \le 10 k\Omega \tag{5}$$

$$R_{FBT} \le 10 \ k\Omega \times \frac{V_{OUT}}{1 \ V} \tag{6}$$

8.2.2.3 Inductor Selection

The parameters for selecting the inductor are the inductance and saturation current. The inductance is based on the desired peak-to-peak ripple current and is normally chosen to be in the range of 20% to 40% of the maximum output current. Note that when selecting the ripple current for applications with much smaller maximum load than the maximum available from the device, use the maximum device current. \pm 7 can be used to determine the value of inductance. The constant K is the percentage of inductor current ripple. For this example, choose K = 0.4 and find an inductance of L = 3.64 μ H. Select the standard value of 3.3 μ H. Note that the inductor values presented in \pm 8-1 and \pm 8-2 were calculated using K= 0.3.

$$L = \frac{(V_{IN} - V_{OUT})}{f_{SW} \times K \times I_{OUTmax}} \times \frac{V_{OUT}}{V_{IN}}$$
(7)

Ideally, the saturation current rating of the inductor is at least as large as the high-side switch current limit, $I_{PEAKMAX}$ (see 2000). This size makes sure that the inductor does not saturate, even during a short circuit on the output. When the inductor core material saturates, the inductance falls to a very low value, causing the inductor current to rise very rapidly. Although the valley current limit, I_{VALMAX} , is designed to reduce the risk of current runaway, a saturated inductor can cause the current to rise to high values very rapidly. This action can lead to component damage. Do not allow the inductor to saturate. Inductors with a ferrite core material have very hard saturation characteristics, but usually have lower core losses than powdered iron cores. Powered iron cores exhibit a *soft* saturation, allowing some relaxation in the current rating of the inductor. However, they have more core losses at frequencies above about 1MHz. In any case, the inductor saturation current must not be less than the maximum peak inductor current at full load.

The maximum inductance is limited by the minimum current ripple for the current mode control to perform correctly. As a rule, the minimum inductor ripple current must be no less than about 10% of the device maximum rated current under nominal conditions.

8.2.2.4 Output Capacitor Selection

The current mode control scheme of the LMR436x0-Q1 devices allows operation over a wide range of output capacitance. The output capacitor bank is usually limited by the load transient requirements and stability rather than the output voltage ripple. Refer to $\frac{1}{5}$ 8-1 for typical output capacitor value for 3.3V and 5V output voltages. Based on $\frac{1}{5}$ 8-1, for a 3.3V 5V output design, you can choose the recommended 2 × 22 μ F ceramic output capacitor for this example. For other designs with other output voltages, WEBENCH can be used as a starting point for selecting the value of output capacitor.

In practice, the output capacitor has the most influence on the transient response and loop-phase margin. Load transient testing and bode plots are the best way to validate any given design and must always be completed before the application goes into production. In addition to the required output capacitance, a small ceramic capacitor placed on the output can help reduce high-frequency noise. Small-case size ceramic capacitors in the range of 1nF to 100nF can be very helpful in reducing spikes on the output caused by inductor and board parasitics.

Limit the maximum value of total output capacitance to about 10 times the design value, or $1000\mu F$, whichever is smaller. Large values of output capacitance can adversely affect the start-up behavior of the regulator as well as the loop stability. If values larger than noted here must be used, then a careful study of start-up at full load and loop stability must be performed.

8.2.2.5 Input Capacitor Selection

The ceramic input capacitors provide a low impedance source to the regulator in addition to supplying the ripple current and isolating switching noise from other circuits. A minimum ceramic capacitance of 4.7µF is required on the input of the LMR436x0-Q1. This must be rated for at least the maximum input voltage that the application requires, preferably twice the maximum input voltage. This capacitance can be increased to help reduce input voltage ripple and maintain the input voltage during load transients. In addition, a small case size 100nF ceramic capacitor must be used at the input, as close a possible to the regulator. In the case of the

LMR43620MQ3EVM-2M this capacitor is placed approximately 0.38mm away from the regulator. This provides a high frequency bypass for the control circuits internal to the device. For this example, a 4.7µF, 50V, X7R (or better) ceramic capacitor is chosen. The 100nF must also be rated at 50V with an X7R dielectric.

It is often desirable to use an electrolytic capacitor on the input in parallel with the ceramics. This is especially true if long leads or traces are used to connect the input supply to the regulator. The moderate ESR of this capacitor can help damp any ringing on the input supply caused by the long power leads. The use of this additional capacitor also helps with voltage dips caused by input supplies with unusually high impedance.

Most of the input switching current passes through the ceramic input capacitor or capacitors. The approximate RMS value of this current can be calculated from 式 8 and must be checked against the manufacturers' maximum ratings.

$$I_{RMS} \cong \frac{I_{OUT}}{2}$$
 (8)

8.2.2.6 CBOOT

The LMR436x0-Q1 requires a bootstrap capacitor connected between the BOOT pin and the SW pin. This capacitor stores energy that is used to supply the gate drivers for the power MOSFETs. A high-quality ceramic capacitor of 100nF and at least 16V is required.

8.2.2.7 VCC

The VCC pin is the output of the internal LDO used to supply the control circuits of the regulator. This output requires a 1μF, 16V ceramic capacitor connected from VCC to GND for proper operation. In general, this output must not be loaded with any external circuitry. However, this output can be used to supply the pullup for the power-good function (see $2992 \times 7.3.4$). A value in the range of $10k\Omega$ to $100k\Omega$ is a good choice in this case. The nominal output voltage on VCC is 3.3V; see *Electrical Characteristics* for limits.

8.2.2.8 C_{FF} Selection

In some cases, a feedforward capacitor can be used across R_{FBT} to improve the load transient response or improve the loop-phase margin. *Optimizing Transient Response of Internally Compensated DC-DC Converters with Feedforward Capacitor Application Report* is helpful when experimenting with a feedforward capacitor.

Due to the nature of the feedback detect circuitry, the value of C_{FF} must be limited to make sure that the desired output voltage is established when configuring for adjustable output voltages. $\stackrel{>}{\lesssim}$ 9 must be followed to make sure C_{FF} remains below the maximum value.

$$C_{FF} < C_{OUT} \times \frac{\sqrt{V_{OUT}}}{12.M0} \tag{9}$$

8.2.2.9 External UVLO

In some cases, an input UVLO level different than that provided internal to the device is needed. This can be accomplished by using the circuit shown in \boxtimes 8-2. The input voltage at which the device turns on is designated as V_{ON} while the turn-off voltage is V_{OFF} . First, a value for R_{ENB} is chosen in the range of $10k\Omega$ to $100k\Omega$, then $\overrightarrow{\pm}$ 10 and $\overrightarrow{\pm}$ 11 are used to calculate R_{ENT} and V_{OFF} respectively.

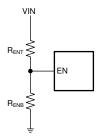

図 8-2. Setup for External UVLO Application

$$R_{ENT} = \left(\frac{V_{ON}}{V_{EN} - V_{OUT}} - 1\right) \times R_{ENB} \tag{10}$$

$$V_{OFF} = V_{ON} \times \left(1 - \frac{V_{EN} - HYS}{V_{EN} - V_{OUT}}\right) \tag{11}$$

where

- V_{ON} is the V_{IN} turn-on voltage.
- V_{OFF} is the V_{IN} turn-off voltage.

8.2.2.10 Maximum Ambient Temperature

As with any power conversion device, the LMR436x0-Q1 dissipates internal power while operating. The effect of this power dissipation is to raise the internal temperature of the converter above ambient. The internal die temperature (T_J) is a function of the ambient temperature, the power loss, and the effective thermal resistance, R_{B.IA}, of the device, and PCB combination. The maximum junction temperature for the LMR436x0-Q1 must be limited to 150°C. This establishes a limit on the maximum device power dissipation and, therefore, the load current. 式 12 shows the relationships between the important parameters. It is easy to see that larger ambient temperatures (TA) and larger values of ROJA reduce the maximum available output current. The converter efficiency can be estimated by using the curves provided in this data sheet. If the desired operating conditions cannot be found in one of the curves, interpolation can be used to estimate the efficiency. Alternatively, the EVM can be adjusted to match the desired application requirements and the efficiency can be measured directly. The correct value of R_{0JA} is more difficult to estimate. For more information reference Semiconductor and IC Package Thermal Metrics Application Report.

$$I_{OUT} \bigg|_{MAX} = \frac{\left(T_J - T_A\right)}{R_{\theta JA}} \times \frac{\eta}{(1 - \eta)} \times \frac{1}{V_{OUT}}$$
(12)

where

• η is the efficiency.

The effective $R_{\theta,IA}$ is a critical parameter and depends on many factors such as the following:

- Power dissipation
- Air temperature/flow
- PCB area
- Copper heat-sink area
- Number of thermal vias under the package
- Adjacent component placement

The IC junction temperature can be estimated for a given operating condition using 式 13.

$$T_I \cong T_A + R_{\theta IA} \times IC \ Power \ Loss$$
 (13)

where

- T_J is the IC junction temperature (${}^{\circ}$ C).
- T_A is the ambient temperature (°C).
- $R_{\theta JA}$ is the thermal resistance (°C/W).
- IC power loss is the power loss for the IC (W).

The IC Power loss mentioned above is the overall power loss minus the loss that comes from the inductor DC resistance. The overall power loss can be approximated by using WEBENCH for a specific operating condition and temperature.

8.3 Best Design Practices

- Do not exceed the Absolute Maximum Ratings.
- Do not exceed the *Recommended Operating Conditions*.
- Do not exceed the ESD Ratings.
- · Do not allow the EN input to float.
- · Do not allow the output voltage to exceed the input voltage, nor go below ground.
- Follow all the guidelines and suggestions found in this data sheet before committing the design to production. TI application engineers are ready to help critique your design and PCB layout to help make your project a success.

8.4 Power Supply Recommendations

$$I_{IN} = \frac{V_{OUT} \times I_{OUT}}{V_{IN} \times \eta} \tag{14}$$

where

n is the efficiency.

If the regulator is connected to the input supply through long wires or PCB traces, special care is required to achieve good performance. The parasitic inductance and resistance of the input cables can have an adverse effect on the operation of the regulator. The parasitic inductance, in combination with the low-ESR, ceramic input capacitors, can form an underdamped resonant circuit, resulting in overvoltage transients at the input to the regulator. The parasitic resistance can cause the voltage at the VIN pin to dip whenever a load transient is applied to the output. If the application is operating close to the minimum input voltage, this dip can cause the regulator to momentarily shut down and reset. The best way to solve these kind of issues is to limit the distance from the input supply to the regulator or plan to use an aluminum or tantalum input capacitor in parallel with the ceramics. The moderate ESR of these types of capacitors help dampen the input resonant circuit and reduce any overshoots. A value in the range of 20 μ F to 100 μ F is usually sufficient to provide input damping and help to hold the input voltage steady during large load transients.

Sometimes, for other system considerations, an input filter is used in front of the regulator. This action can lead to instability, as well as some of the effects mentioned above, unless designed carefully. The AN-2162 Simple Success With Conducted EMI From DC/DC Converters Application Report provides helpful suggestions when designing an input filter for any switching regulator.

In some cases, a transient voltage suppressor (TVS) is used on the input of regulators. One class of this device has a *snap-back* characteristic (thyristor type). TI does not recommend the use of a device with this type of characteristic. When the TVS fires, the clamping voltage falls to a very low value. If this voltage is less than the output voltage of the regulator, the output capacitors discharge through the device back to the input. This uncontrolled current flow can damage the device.

8.5 Layout

8.5.1 Layout Guidelines

The PCB layout of any DC/DC converter is critical to the optimal performance of the design. Poor PCB layout can disrupt the operation of an otherwise good schematic design. Even if the converter regulates correctly, bad PCB layout can mean the difference between a robust design and one that cannot be mass produced. Furthermore, to a great extent, the EMI performance of the regulator is dependent on the PCB layout. In a buck converter, the most critical PCB feature is the loop formed by the input capacitor or capacitors and power ground, as shown in 🗵 8-31. This loop carries large transient currents that can cause large transient voltages when reacting with the trace inductance. These unwanted transient voltages disrupt the proper operation of the converter. Because of this, the traces in this loop must be wide and short, and the loop area as small as possible

English Data Sheet: SNVSBE0

to reduce the parasitic inductance. \boxtimes 8-32 shows a recommended layout for the critical components of the LMR436x0-Q1.

- Place the input capacitors as close as possible to the VIN and GND terminals.
- Place bypass capacitor for VCC close to the VCC pin. This capacitor must be placed close to the device and routed with short, wide traces to the VCC and GND pins.
- Use wide traces for the C_{BOOT} capacitor. Place C_{BOOT} close to the device with short/wide traces to the BOOT and SW pins.
- Place the feedback divider as close as possible to the FB pin of the device. Place R_{FBB}, R_{FBT}, and C_{FF}, if used, physically close to the device. The connections to FB and GND must be short and close to those pins on the device. The connection to V_{OUT} can be somewhat longer. However, the latter trace must not be routed near any noise source (such as the SW node) that can capacitively couple into the feedback path of the regulator.
- Use at least one ground plane in one of the middle layers. This plane acts as a noise shield and as a heat dissipation path.
- Provide wide paths for VIN, VOUT, and GND. Making these paths as wide and direct as possible reduces any voltage drops on the input or output paths of the converter and maximizes efficiency.
- Provide enough PCB area for proper heat-sinking. As stated in セクション 8.2.2.10, enough copper area must be used to make sure a low R_{θJA}, commensurate with the maximum load current and ambient temperature. The top and bottom PCB layers must be made with two ounce copper and no less than one ounce. If the PCB design uses multiple copper layers (recommended), these thermal vias can also be connected to the inner layer heat-spreading ground planes.
- Keep switch area small. Keep the copper area connecting the SW pin to the inductor as short and wide as possible. At the same time, the total area of this node must be minimized to help reduce radiated EMI.

8.5.1.1 Ground and Thermal Considerations

As previously mentioned, TI recommends using one of the middle layers as a solid ground plane. A ground plane provides shielding for sensitive circuits and traces as well as a quiet reference potential for the control circuitry. Connect the GND pin to the ground planes using vias next to the bypass capacitors. The GND trace, as well as the VIN and SW traces, must be constrained to one side of the ground planes. The other side of the ground plane contains much less noise; use for sensitive routes.

TI recommends providing adequate device heat-sinking by having enough copper near the GND pin. See \boxtimes 8-32 for example layout. Use as much copper as possible, for system ground plane, on the top and bottom layers for the best heat dissipation. Use a four-layer board with the copper thickness for the four layers, starting from the top as: 2 oz / 1 oz / 2 oz. A four-layer board with enough copper thickness, and proper layout, provides low current conduction impedance, proper shielding and lower thermal resistance.

⁽¹⁾ The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

(2) RoHS: TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (CI) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

⁽³⁾ MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

⁽⁴⁾ There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.
