IAR workarounds for msp430 hardware issues

5 Nomenclature, Package Symbolization, and Revision Identification

The revision of the device can be identified by the revision letter on the Package Markings or by the HW_ID located inside the TLV structure of the device.

5.1 Device Nomenclature

To designate the stages in the product development cycle, TI assigns prefixes to the part numbers of all MSP MCU devices. Each MSP MCU commercial family member has one of two prefixes: MSP or XMS. These prefixes represent evolutionary stages of product development from engineering prototypes (XMS) through fully qualified production devices (MSP).

XMS – Experimental device that is not necessarily representative of the final device's electrical specifications

MSP - Fully qualified production device

Support tool naming prefixes:

X: Development-support product that has not yet completed Texas Instruments internal qualification testing.

null: Fully-qualified development-support product.

XMS devices and X development-support tools are shipped against the following disclaimer:

"Developmental product is intended for internal evaluation purposes."

MSP devices have been characterized fully, and the quality and reliability of the device have been demonstrated fully. Tl's standard warranty applies.

Predictions show that prototype devices (XMS) have a greater failure rate than the standard production devices. TI recommends that these devices not be used in any production system because their expected end-use failure rate still is undefined. Only qualified production devices are to be used.

TI device nomenclature also includes a suffix with the device family name. This suffix indicates the temperature range, package type, and distribution format.

5.2 Package Markings

PZ100 LQFP (PZ) 100 Pin

NOTE: Package marking with "TM" applies only to devices released after 2011.

5.3 Memory-Mapped Hardware Revision (TLV Structure)

This device does not support reading the hardware revision from memory.

Further guidance on how to locate the TLV structure and read out the HW_ID can be found in the device User's Guide.

6 Advisory Descriptions

COMP3 COMP Module

Category Functional

Function Control bits for comparator analog inputs not functional.

Description Bits P2CA0 and P2CA1 in CACTL2 used to connect the CA0 and CA1 device pins to the

comparator module, respectively, have no effect when set to "1". The external connections to the comparator inputs are controlled instead by the CAPDx bits for the respective CA0 and CA1 port pins. (By definition, the CAPDx bits are used to disable the GPIO logic for

each associated port pin.)

Workaround The CA0 and CA1 external inputs can be connected to the comparator internally

by setting the bits CAPD6=1 and CAPD7=1 respectively. To disconnect an external analog signal from the CA0 or CA1 comparator inputs, CAPD6 or CAPD7 are cleared. Additionally in this case, the GPIO logic is no longer disabled and an external analog signal at the port input may cause increased current consumption through the digital input structure on the order of tens of microamps; the input leakage current is not affected.

CPU19 CPU Module

Category Compiler-Fixed

Function CPUOFF modification may result in unintentional register read

Description If an instruction that modifies the CPUOFF bit in the Status Register is followed by an

instruction with an indirect addressed operand (e.g. MOV @R8, R9, RET, POP, POPM), an unintentional register read operation can occur during the wakeup of the CPU. If the unintentional read occurs to a read sensitive register (e.g. UCB0RXBUF, TAIV), which changes its value or the value of other registers (IFG's), the bug leads to lost interrupts or

wrong register read values.

Workaround Insert a NOP instruction after each CPUOFF instruction.

OR

Refer to the table below for compiler-specific fix implementation information. Note that compilers implementing the fix may lead to double stack usage when RET/RETA follows the compiler-inserted NOP.

IDE/Compiler	Version Number	Notes
IAR Embedded Workbench	IAR EW430 v6.20.1 until v6.40	User is required to add the compiler or assembler flag option below hw_workaround=nop_after_lpm

CPU44 CPU Module

Category Functional

Function Incorrect address fetching during interrupt decoding

Description The CPU uses the default reset address if an interrupt is fired during the same time

window as the module interrupt is being disabled. The failure only occurs at high temperature and/or when the frequency is near the maximum allowable range for the

current VCC.

Workaround 1) Keep the system frequency lower from the maximum allowable value for the system

VCC. OR

2) Use the DINT before clearing the module interrupt enable (IE) bit.

Example for USCI_A0:

```
__disable_interrupt();  // Workaround
IE2 &= ~(UCAOTXIE);
__enable_interrupt();
```

EEM20 EEM Module

Category Debug

Function Debugger might clear interrupt flags

Description During debugging read-sensitive interrupt flags might be cleared as soon as the debugger

stops. This is valid in both single-stepping and free run modes.

Workaround None.

FLASH19 FLASH Module

Category Functional

Function EEI feature does not work for code execution from RAM

Description When the program is executed from RAM, the flash controller EEI feature does not work.

The erase cycle is suspended and the interrupt is serviced, but there is a problem while

resuming with the erase cycle.

Addresses applied to flash are different than the actual values while resuming erase cycle after ISR execution.

Workaround

None

FLASH24 FLASH Module

Category

Functional

Function

Write or erase emergency exit can cause failures

Description

When a flash write or erase is abruptly terminated, the following flash accesses by the CPU may be unreliable resulting in erroneous code execution. The abrupt termination can be the result of one the following events:

1) The flash controller clock is configured to be sourced by an external crystal. An oscillator fault occurs thus stopping this clock abruptly.

or

2) The Emergency Exit bit (EMEX in FCTL3) when set forces a write or an erase operation to be terminated before normal completion.

or

3) The Enable Emergency Interrupt Exit bit (EEIEX in FCTL1) when set with GIE=1 can lead to an interrupt causing an emergency exit during a Flash operation.

Workaround

1) Use the internal DCO as the flash controller clock provided from MCLK or SMCLK.

or

2) After setting EMEX = 1, wait for a sufficient amount of time before Flash is accessed again.

or

3) No Workaround. Do not use EEIEX bit.

FLASH25 FLASH Module

Category

Functional

Function

Marginal Read Mode is not functional

Description

The control bits for marginal read mode contained in the FCTL4 register are automatically cleared by any flash access. This prevents the marginal read mode from being used.

Workaround

It is possible to read out memory contents in marginal read mode if the indexed addressing mode X(Ry) is used to access the flash memory. In this case, the FCTL4 control bits are not cleared, and the marginal read mode works as expected. It is recommended to write the code for reading the flash memory contents in assembler as this allows full control over the used addressing mode. Note that certain assemblers may optimize an indexed addressing source operation of 0(Ry) to an indirect register mode @Ry operation, which will not work. The following is an example of reading the word memory location 0x4000 in marginal read mode, preventing a possible assembler optimization:

mov.w #0x4000,R15; Pointer to target address

dec.w R15; Decrement pointer

mov.w 1(R15),R12; Read memory contents at R15+1, store result in R12

FLASH27 FLASH Module

Category Functional

www.ti.com Advisory Descriptions

Function EEI feature can disrupt segment erase

Description When a flash segment erase operation is active with EEI feature selected (EEI=1 in

FLCTL1) and GIE=0, the following can occur:

An interrupt event causes the flash erase to be stopped, and the flash controller expects an RETI to resume the erase. Because GIE=0, interrupts are not serviced and RETI will

never happen.

Workaround 1) Do not set bit EEI=1 when GIE = 0.

or,

2) Force an RETI instruction during the erase operation during the check for BUSY=1

(FCLTL3).

Sample code:

MOV R5, 0(R5); Dummy write, erase segment LOOP: BIT #BUSY, &FCTL3; test busy bit JMP SUB_RETI; Force RETI instruction

JNZ LOOP; loop while BUSY=1

SUB RETI: PUSH SR

RETI

FLASH36 FLASH Module

Category Functional

Function Flash content may degrade due to aborted page erases

Description If a page erase is aborted by EEIEX, the flash page containing the last instruction before

erase operation will start to degrade. This effect is incremental and, after repetitions, may

lead to corrupted flash content.

Workaround - Use the EEI (interrupted erasing) feature instead of EEIEX (abort erasing).

or

- A PSA checksum can be calculated over affected flash page using the marginal read mode (marginal 0). If PSA sum differs from expected PSA value the affected flash page

has to be reprogrammed.

or

- Start flash erasing from RAM and limit system frequency to <1MHz (to ensure 6-us delay after EEIEX). If the last instruction before erasing is located in RAM, flash cell degradation

does not occur.

FLL4 FLL Module

Category Functional

Function Unexpected behavior of bit XT20FF

Description If MCLK and/or SMCLK are configured to operate with the external crystal XT2

(SELMx=10b, and/or SELS=1), modification of the bit XT2OFF from 0 to 1 in register FLL_CTL1 thereafter should not turn off XT2. This feature is not functional and the

following two conditions occur

1) XT2 is switched OFF, MCLK is set to DCO frequency and SMCLK is turned OFF

And.

2) OFIFG bit in IFG1 register is set to 1

Workaround

Oscillator Fault interrupt (OFIE bit in IE1 register) can be enabled. Follow the User's Guide instructions to use the NMI Interrupt Handler to check for OFIFG=1. Additionally check for XT2OFF=1 and clear this bit to re-enable XT2.

FLL5 FLL Module

Category Functional

Function Incorrect SMCLK request in low power modes

Description If SMCLK is configured to be sourced by XT2 and if bit SCG1=1 in SR (to enter specific

low-power modes), SMCLK if not being used by any peripheral, should turn OFF when SMCLKOFF=1 (FLL_CTL1). However, SMCLK continues to remain active with no effect of

SMCLKOFF=1.

Workaround To turn off SMCLK sourced by XT2 for specific low-power modes follow the sequence

below:

1) Set SMCLKOFF=1

2) Configure SMCLK to be sourced by DCO (SELS=0)

3) Enter desired low-power mode

FLL6 FLL Module

Category Functional

Function LFXT1DIG bit is read incorrectly

Description The LFXT1DIG bit always reads as '0' even when the bit is programmed to '1'. This affects

only the readout of the bit and not the clock bypass implementation which functions as

expected.

Workaround None

FLL7 FLL Module

Category Functional

Function Flash operations using MCLK as the source may be affected

Description Flash write and erase operations that take place with the flash controller using MCLK as

the source are not guaranteed to complete as expected under the following conditions:

1) When MCLK is sourced by an external clock source such as LFXT1 or XT2 and a clock

fail condition occurs.

2) When MCLK is sourced from the DCOCLK by setting SELMx = 01 in FLL CTL1

register.

Workaround 1)If MCLK is used as the clock source for the flash controller (FSSEL_01.FCTL2), always

source MCLK from DCO by setting SELMx = 00 in the FLL CTL1 register.

OR

2)Use ACLK or SMCLK as the clock source for the flash controller. In this case, if the

external clock source fails, the clock fail indication works as expected.

JTAG23 JTAG Module

www.ti.com Advisory Descriptions

Category Debug

Function PSA checksum calculation does not work in marginal read mode.

Description If the PSA checksum is calculated via JTAG interface in marginal read mode the MRG0

and MRG1 bits in the FCTL4 register are reset.

Workaround None.

LCDA5 LCDA Module

Category Functional

Function Wrong cycle time for first cycle of COMx/Sx signals

Description The time of the first cycle of COMx/Sx signals after enabling the LCD_A module is only

half of the selected value. All following cycles are correct

Workaround Not required, because it does not influence the LCD function.

LCDA7 LCDA Module

Category Functional

Function Higher current consumption when using shared LCD ports as fast toggling outputs

Description If a shared LCD pin (segment or com line) is used as digital fast toggling output (f>10kHz)

and the VLCD is >0V (BG enabled) the device current consumption increases with higher

toggling frequencies.

Workaround 1. Do not use shared LCD pins as fast toggling outputs if an LCD is used.

2. Reduce the toggle frequency of the shared pin to <10kHz.

SDA4 SDA Module

Category Functional

Function Reduced SINAD performance at certain input voltage levels

Description The performance of the SD16_A maybe degraded due to reduced SINAD when the

level of the analog input is between 20mV and 120mV. This can occur on any channel,

irrespective of their PGA settings.

Workaround 1. Avoid the use of any PGA settings less than 16 with the common-mode voltage of zero,

which most likely accommodates input signal levels that fall under this range.

or

2. Introduce a common-mode voltage, such as internal reference voltage of 1.2 V, to

ensure that the input signal level is outside the range of 20 mV to 120 mV.

The following table shows the SD16_A performance with common mode voltage of zero:

Advisory Descriptions Support Support

SD16_A, performance ($f_{SD16} = 1 \text{ MHz}$, SD16OSRx = 256, SD16REFON = 1)

TA12 TA Module

Category Functional

Function Interrupt is lost (slow ACLK)

Description Timer A counter is running with slow clock (external TACLK or ACLK) compared to MCLK.

The compare mode is selected for the capture/compare channel and the CCRx register is incremented by one with the occurring compare interrupt (if TAR = CCRx). Due to the fast MCLK the CCRx register increment (CCRx = CCRx+1) happens before the Timer_A counter has incremented again. Therefore the next compare interrupt should happen at once with the next Timer_A counter increment (if TAR = CCRx + 1). This interrupt gets

lost.

Workaround Switch capture/compare mode to capture mode before the CCRx register increment.

Switch back to compare mode afterwards.

TA16 TA Module

Category Functional

Function First increment of TAR erroneous when IDx > 00

Description The first increment of TAR after any timer clear event (POR/TACLR) happens immediately

following the first positive edge of the selected clock source (INCLK, SMCLK, ACLK or TACLK). This is independent of the clock input divider settings (ID0, ID1). All following

TAR increments are performed correctly with the selected IDx settings.

Workaround None

TA21 TA Module

Category Functional

Function TAIFG Flag is erroneously set after Timer A restarts in Up Mode

Description In Up Mode, the TAIFG flag should only be set when the timer counts from TACCR0 to

zero. However, if the Timer A is stopped at TAR = TACCR0, then cleared (TAR=0) by setting the TACLR bit, and finally restarted in Up Mode, the next rising edge of the TACLK

will erroneously set the TAIFG flag.

Workaround None.

TAB22 TAB Module

Category Functional

Function Timer A/Timer B register modification after Watchdog Timer PUC

Description Unwanted modification of the Timer A/Timer B registers TACTL/TBCTL and TAIV/TBIV

can occur when a PUC is generated by the Watchdog Timer(WDT) in Watchdog mode and any Timer_A/Timer_B counter register TACCRx/TBCCRx is incremented/

decremented (Timer_A/Timer_B does not need to be running).

Workaround Initialize TACTL/TBCTL register after the reset occurs using a MOV instruction (BIS/BIC

may not fully initialize the register). TAIV/TBIV is automatically cleared following this

initialization.

Example code:

MOV.W #VAL, &TACTL

or

MOV.W #VAL, &TBCTL

Where, VAL=0, if Timer is not used in application otherwise, user defined per desired

function.

TB2 TB Module

Category Functional

Function Interrupt is lost (slow ACLK)

Description Timer B counter is running with slow clock (external TBCLK or ACLK) compared to

MCLK. The compare mode is selected for the capture/compare channel and the CCRx register is incremented by 1 with the occurring compare interrupt (if TBR = CCRx). Due to the fast MCLK, the CCRx register increment (CCRx = CCRx + 1) happens before the Timer_B counter has incremented again. Therefore, the next compare interrupt should happen at once with the next Timer_B counter increment (if TBR = CCRx + 1). This

interrupt is lost.

Workaround Switch capture/compare mode to capture mode before the CCRx register increment.

Switch back to compare mode afterward.

TB16 TB Module

Category Functional

Function First increment of TBR erroneous when IDx > 00

Description The first increment of TBR after any timer clear event (POR/TBCLR) happens

immediately following the first positive edge of the selected clock source (INCLK, SMCLK, ACLK, or TBCLK). This is independent of the clock input divider settings (ID0, ID1). All following TBR increments are performed correctly with the selected IDx settings.

Workaround None

TB24 TB Module

Category Functional

Function TBIFG Flag is erroneously set after Timer B restarts in Up Mode

Description

In Up Mode, the TBIFG flag should only be set when the timer resets from TBCCR0 to zero. However, if the Timer B is stopped at TBR = TBCCR0, then cleared (TBR=0) by setting the TBCLR bit, and finally restarted in Up Mode, the next rising edge of the TBCLK will erroneously set the TBIFG flag.

Workaround None.

USCI15 USCI Module

Category Functional

Function Receive buffer overrun undetected

Description When a new character is being loaded into RXBUF by the USCI hardware, the previous

character may be overwritten. This can occur when the USCI hardware updates RXBUF with the new character and in the same instant the CPU accesses RXBUF to read the old character. In this case, the old character is lost and the new one is read out. No receive

overrun error will be detected and UCOE will not be set.

Workaround Running the CPU at an adequate speed in order to guarantee access of RXBUF of

received characters prior to new character receive completion will minimize the potential

that simultaneous access of RXBUF may happen.

USCI19 USCI Module

Category Functional

Function LPM4 may affect USCI operation

Description When SMCLK is used as the USCI clock source, and SMCLK gets deactivated due to

a LPM4 entry, ongoing SPI master, I2C master, and UART transmit transaction will be

interrupted. Also, while in LPM4, UART receive operation is non-functional.

www.ti.com Advisory Descriptions

Workaround

Do not enter LPM4 while SPI master, I2C master, or UART transmit operations are active. Wait for the operation to be completed prior entering LPM4, or enter a different low-power mode instead. Also, do not use LPM4 in case of UART receive operation. Instead, use a different low-power mode.

USCI20 USCI Module

Category Functional

Function I2C Mode Multi-master transmitter issue

Description When configured for I2C master-transmitter mode, and used in a multi-master

environment, the USCI module can cause unpredictable bus behavior if all of the following

four conditions are true:

1 - Two masters are generating SCL

And

2 - The slave is stretching the SCL low phase of an ACK period while outputting NACK on

SDA And

3 - The slave drives ACK on SDA after the USCI has already released SCL, and then the

SCL bus line gets released

And

4 - The transmit buffer has not been loaded before the other master continues

communication by driving SCL low

The USCI will remain in the SCL high phase until the transmit buffer is written. After the transmit buffer has been written, the USCI will interfere with the current bus activity and may cause unpredictable bus behavior.

may cause unpredictable bus beliavio

Workaround 1 - Ensure that slave doesn't stretch the SCL low phase of an ACK period

Or

2 - Ensure that the transmit buffer is loaded in time

Or

3 - Do not use the multi-master transmitter mode

USCI21 USCI Module

Category Functional

Function UART IrDA receive filter

Description The IrDA receive filter can be used to filter pulses with length UCAIRRXFL configured

in UCAxIRRCTL register. If UCIRRXFE is set the IrDA receive decoder may filter out pulses longer than the configured filter length depending on frequency of BRCLK. This is

resulting in framing errors or corrupted data on the receiver side.

Workaround Depending on the used baud rate and the configured filter length a maximum frequency

for BRCLK needs to be set to avoid this issue:

For baud rates equal and higher than 115.000 the maximum allowed BRCLK frequency is

equal to the max specified system frequency.

Max BRCLK =
$$\frac{\text{Filter Length} + 64}{2} \times \frac{\text{Baud Rate} \times 16}{3 \times 10^6}$$

Baud Rate	Filter Length UCIRRXFL (dec)	Max BRCLK (MHz)

USCI22 USCI Module

Category Functional

Function I2C Master Receiver with 10-bit slave addressing

DescriptionUnexpected behavior of the USCI_B can occur when configured in I2C master receive mode with 10-bit slave addressing under the following conditions:

- 1) The USCI sends first byte of slave address, the slave sends an ACK and when second address byte is sent, the slave sends a NACK.
- 2) Master sends a repeat start condition (If UCTXSTT=1).
- 3) The first address byte following the repeated start is acknowledged.

However, the second address byte is not sent, instead the Master incorrectly starts to receive data and sets UCBxRXIFG=1.

Workaround Do not use repeated start condition instead set the stop condition UCTXSTP=1 in the

Do not use repeated start condition instead set the stop condition UCTXSTP=1 in the NACK ISR prior to the following start condition (USTXSTT=1).

USCI23 USCI Module

www.ti.com Advisory Descriptions

Category Functional

Function UART transmit mode with automatic baud rate detection

Description Erroneous behavior of the USCI_A can occur when configured in UART transmit mode

with automatic baud rate detection. During transmission if a "Transmit break" is initiated (UCTXBRK=1), the USCI A will not deliver a stop bit of logic high, instead, it will send a

logic low during the subsequent synch period.

Workaround 1) Follow User's Guide instructions for transmitting a break/synch field following

ÚCSWRST=1.

Or,

2) Set UCTXBRK=1 before an active transmission, i.e. check for bit UCBUSY=0 and then

set UCTXBRK=1.

USCI24 USCI Module

Category Functional

Function Incorrect baud rate information during UART automatic baud rate detection mode

Description Erroneous behavior of the USCI A can occur when configured in UART mode with

automatic baud rate detection. After automatic baud rate measurement is complete, the UART updates UCAxBR0 and UCAxBR1. Under Oversampling mode (UCOS16=1), for baud rates that should result in UCAxBRx=0x0002, the UART incorrectly reports it as

UCAxBRx=0x5555.

Workaround When break/synch is detected following the automatic baud rate detection, the flag

UCBRK flag is set to 1. Check if UCAxBRx=0x5555 and correct it to 0x0002.

USCI25 USCI Module

Category Functional

Function TXIFG is not reset when NACK is received in I2C mode

Description When the USCI_B module is configured as an I2C master transmitter the TXIFG is not

reset after a NACK is received if the master is configured to send a restart (UCTXSTT=1

& UCTXSTP=0).

Workaround Reset TXIFG in software within the NACKIFG interrupt service routine

Function Tbuf parameter violation in I2C multi-master mode

Description In multi-master I2C systems the timing parameter Tbuf (bus free time between a stop

condition and the following start) is not guaranteed to match the I2C specification of 4.7us in standard mode and 1.3us in fast mode. If the UCTXSTT bit is set during a running I2C transaction, the USCI module waits and issues the start condition on bus release causing

the violation to occur.

Note: It is recommended to check if UCBBUSY bit is cleared before setting UCTXSTT=1.

Workaround None

USCI28 USCI Module

Category

Functional

Function

Timing of USCI I2C interrupts may cause device reset due to automatic clear of an IFG.

Description

When certain USCI I2C interrupt flags (IFG) are set and an automatic flag-clearing event on the I2C bus occurs, it results in an errant ISR call to the reset vector. This will only happen when the IFG is cleared within a critical time window (~6 CPU clock cycles) after a USCI interrupt request occurs and before the interrupt servicing is initiated. The affected interrupts are UCBxTXIFG, UCSTPIFG, UCSTTIFG and UCNACKIFG.

The automatic flag-clearing scenarios are described in the following situations:

- (1) A pending UCBxTXIFG interrupt request is cleared on the falling SCL clock edge following a NACK.
- (2) A pending UCSTPIFG, UCSTTIFG, or UCNACKIFG interrupt request is cleared by a following Start condition.

Workaround

 $\begin{tabular}{ll} (1) Polling the affected flags instead of enabling the interrupts. \end{tabular}$

or

- (2) Ensuring the above mentioned flag-clearing events occur after a time delay of 6 CPU clock cycles has elapsed since the interrupt request occurred and was accepted.
- (3) At program start, check any applicable enabled IE bits such as UCBxTXIE, UCBxRXIE, UCSTTIE, UCSTPIE or UCNACKIE for a reset (A PUC will clear all of the IE bits of interest). If no PUC occurred then the device ran into the above mentioned errant condition and the program counter will need to be restored using an RETI instruction.

; ------ Workaround (3) example for TXIFG ------

Note: For assembly code use code snippet shown below and insert prior to user code

main

bit.b #UCBxTXIE ,&IE2; if TXIE is set, errant call occurred jz start_normal; if not start main program reti; else return from interrupt call start normal

...; Application code continues

Note: For C code the workaround will need to be executed prior to the CSTARTUP routine. The steps for modifying the CSTARTUP routine are IDE dependent. Examples for Code Composer and IAR Embedded Workbench are shown below.

IAR Embedded Workbench:

- 1) The file cstartup.s43 is found at: ...\IAR Systems\< Current Embedded Workbench Version >\430\src\lib\430
- 2) Create a local copy of this file and link it to the project. Do not rename the file.
- 3) In the copy insert the following code prior to stack pointer initialization as shown:

#define IE2 (0x0001)

BIT.B #0x08,&IE2; if TXIE is set, errant call occurred

JZ Start_Normal ; if not start main program

RETI; else return from interrupt call

// Initialize SP to point to the top of the stack.

Start_Normal

MOV #SFE(CSTACK), SP

// Ensure that main is called.

Code Composer:

- 1) The file boot.c is found at ...\Texas Instruments\< Current Code Composer Version > \tools\compiler\MSP430\lib\rtssrc.zip
- 2) Extract the file from rtssrc.zip and create a local copy. Link the copy to the project. Do not rename this file.
- 3) In the copy insert the following code prior to stack pointer initialization as shown:

```
__asm("\t BIT.B\t #0x08,&0x0001"); // if TXIE is set, errant call occurred
  asm("\t JZ\t Start_Normal"); // if not start main program
  asm("\t RETI"); // else return from interrupt call
  asm("Start Normal");
/* Initialize stack pointer. Stack grows toward lower memory. */
Insert the code here:
/* C_INT00() - C ENVIRONMENT ENTRY POINT */
#pragma CLINK( c int00)
extern void __interrupt _c_int00()
{
//
STACK INIT();
```

Function

I2C mode master receiver / slave receiver

Description

When the USCI I2C module is configured as a receiver (master or slave), it performs a double-buffered receive operation. In a transaction of two bytes, once the first byte is moved from the receive shift register to the receive buffer the byte is acknowledged and the state machine allows the reception of the next byte.

If the receive buffer has not been cleared of its contents by reading the UCBxRXBUF register while the 7th bit of the following data byte is being received, an error condition may occur on the I2C bus. Depending on the USCI configuration the following may occur:

- 1) If the USCI is configured as an I2C master receiver, an unintentional repeated start condition can be triggered or the master switches into an idle state (I2C communication aborted). The reception of the current data byte is not successful in this case.
- 2) If the USCI is configured as I2C slave receiver, the slave can switch to an idle state stalling I2C communication. The reception of the current data byte is not successful in this case. The USCI I2C state machine will notify the master of the aborted reception with a NACK.

Note that the error condition described above occurs only within a limited window of the

7th bit of the current byte being received. If the receive buffer is read outside of this window (before or after), then the error condition will not occur.

Workaround

a) The error condition can be avoided altogether by servicing the UCBxRXIFG in a timely manner. This can be done by (a) servicing the interrupt and ensuring UCBxRXBUF is read promptly or (b) Using the DMA to automatically read bytes from receive buffer upon UCBxRXIFG being set.

OR

b) In case the receive buffer cannot be read out in time, test the I2C clock line before the UCBxRXBUF is read out to ensure that the critical window has elapsed. This is done by checking if the clock line low status indicator bit UCSCLLOW is set for atleast three USCI bit clock cycles i.e. 3 X t(BitClock).

Note that the last byte of the transaction must be read directly from UCBxRXBUF. For all other bytes follow the workaround:

Code flow for workaround

- (1) Enter RX ISR for reading receiving bytes
- (2) Check if UCSCLLOW.UCBxSTAT == 1
- (3) If no, repeat step 2 until set
- (4) If yes, repeat step 2 for a time period > 3 x t (BitClock) where t (BitClock) = 1/ f (BitClock)
- (5) If window of 3 x t(BitClock) cycles has elapsed, it is safe to read UCBxRXBUF

USCI34 USCI Module

Category

Functional

Function

I2C multi-master transmit may lose first few bytes.

Description

In an I2C multi-master system (UCMM =1), under the following conditions:

(1)the master is configured as a transmitter (UCTR =1)

AND

(2)the start bit is set (UCTXSTT =1);

if the I2C bus is unavailable, then the USCI module enters an idle state where it waits and checks for bus release. While in the idle state it is possible that the USCI master updates its TXIFG based on clock line activity due to other master/slave communication on the bus. The data byte(s) loaded in TXBUF while in idle state are lost and transmit pointers initialized by the user in the transmit ISR are updated incorrectly.

Workaround

Verify that the START condition has been sent (UCTXSTT =0) before loading TXBUF with data.

```
Example:
```

```
#pragma vector = USCIAB0TX_VECTOR
__interrupt void USCIAB0TX_ISR(void)
{
// Workaround for USCI34
if(UCB0CTL1&UCTXSTT)
{
```

```
// TXData = pointer to the transmit buffer start
// PTxData = pointer to transmit in the ISR
PTxData = TXData; // restore the transmit buffer pointer if the Start bit is set
}
//
if(IFG2&UCB0TXIFG)
{
   if (PTxData < = PTxDataEnd) // Check TX byte counter
{
     UCB0TXBUF = *PTxData++; // Load TX buffer
}
   else
{
     UCB0CTL1 |= UCTXSTP; // I2C stop condition
     IFG2 &= ~UCB0TXIFG; // Clear USCI_B0 TX int flag
     __bic_SR_register_on_exit(CPUOFF); // Exit LPM0
}
}</pre>
```

USCI35 USCI Module

Category Functional

Function Violation of setup and hold times for (repeated) start in I2C master mode

Description In I2C master mode, the setup and hold times for a (repeated) START, t_{SU,STA} and t_{HD,STA}

respectively, can be violated if SCL clock frequency is greater than 50kHz in standard mode (100kbps). As a result, a slave can receive incorrect data or the I2C bus can be

stalled due to clock stretching by the slave.

Workaround If using repeated start, ensure SCL clock frequencies is < 50kHz in I2C standard mode

(100 kbps).

USCI40 USCI Module

Category Functional

Function SPI Slave Transmit with clock phase select = 1

Description In SPI slave mode with clock phase select set to 1 (UCAxCTLW0.UCCKPH=1), after the

first TX byte, all following bytes are shifted by one bit with shift direction dependent on UCMSB. This is due to the internal shift register getting pre-loaded asynchronously when writing to the USCIA TXBUF register. TX data in the internal buffer is shifted by one bit

after the RX data is received.

Workaround Reinitialize TXBUF before using SPI and after each transmission.

If transmit data needs to be repeated with the next transmission, then write back

previously read value:

UCAxTXBUF = UCAxTXBUF;

XOSC5 XOSC Module

Category Functional

Function LF crystal failures may not be properly detected by the oscillator fault circuitry

Description The oscillator fault error detection of the LFXT1 oscillator in low frequency mode (XTS =

0) may not work reliably causing a failing crystal to go undetected by the CPU, i.e. OFIFG

will not be set.

Workaround None

XOSC8 XOSC Module

Category Functional

Function ACLK failure when crystal ESR is below 40 kOhm.

Description When ACLK is sourced by a low frequency crystal with an ESR below 40 kOhm, the duty

cycle of ACLK may fall below the specification; the OFIFG may become set or in some

instances, ACLK may stop completely.

Workaround Please refer to "XOSC8 Guidance" found at SLAA423 for information regarding working

with this erratum.

XOSC9 XOSC Module

Category Functional

Function XT1 Oscillator may not function as expected in HF mode

Description XT1 oscillator does not work correctly in high frequency mode at supply voltages below

2.0V with crystal frequency > 4MHz.

Workaround None. When XT1 oscillator is used in HF mode with crystal frequency > 4MHz ensure a

supply voltage > 2.2V.
